VOLUME 1

Chapter 1	Language Assessment of Action/Verb Processing in Patients with Parkinson's Disease: A Critical Analysis Through the Multilevel Model <i>Maria Teresa Carthery-Goulart, Henrique Salmazo da Silva, Juliana Bruno Machado, Roberta Roque Baradel and Maria Alice de Mattos Pimenta Parente</i>	3
Chapter 2	Prevalence of Speech and Language Disorders: Identify and Outcome at the Learning Disabilities <i>Montfragüe García-Mateos, Luz María Fernández Mateos and Javier De Santiago Herrero</i>	29
Chapter 3	Language Development as a Marker of Normal Brain Development <i>Robert Perna, Ashlee R. Loughan, Stephanie Northington and Hana Perkey</i>	47
Chapter 4	Atypical Language Development and Psychopathological Risk: A Typical Neuropsychiatric Problem? <i>Matteo Alessio Chiappedi, Michela Tantardini, Giulia Burrone and Ilaria Maria Carlotta Baschenis</i>	67
Chapter 5	Intercultural Nonverbal Communication Competence: Meeting Body Language Challenges in Facilitating and Working with Students from Culturally Diverse Backgrounds in the Australian Higher Education Context <i>Ping Yang</i>	83
Chapter 6	Phone Duration Modeling of the Serbian Language: Comparative Evaluation of Different Models <i>Sandra Sovilj-Nikić and Ivan Sovilj-Nikić</i>	99

Chapter 7	Inferential Comprehension in a Dialogic Reading Task: Comparing 5-Year-Old Children with Specific Language Impairment to Typically Developing Peers <i>Paméla Filiatrault-Veilleux, Geneviève Tarte and Chantal Desmarais</i>	121
Chapter 8	Virtual Avatar Signing in Real Time as Classroom Support for Deaf Students <i>Lucia Vera, Inmaculada Coma, Julio Campos, Bibiana Martínez and Marcos Fernández</i>	137
Chapter 9	Perceived Communication Ability of Open Question Interview in Individuals with Traumatic Brain Injury (TBI): Using La Trobe Communication Questionnaire <i>Keiko Matsuoka, Izumi Kotani and Michihiko Yamasato</i>	155
Chapter 10	Analysis of Nonverbal Behavior in Affective Disorders in Children and Adolescents with Type 1 Diabetes <i>Oleg A. Gilburd, Jana V. Girsh and Nadezhda A. Donnikova</i>	171
Chapter 11	Establishing Grammatical Cohesion in Kenyan Sign Language (KSL) Formal Discourse: The Case of a Sermon Delivered in KSL <i>Jefwa G. Mweri</i>	181
Chapter 12	Method and Materials for a Computer-Based Test of Sign Language Ability: The American Sign Language Discrimination Test (ASL-DT) <i>Joseph Bochner, Wayne Garrison, Kim Kurz, Jason Listman, Vincent Samar and Deirdre Schlehofer</i>	219
Chapter 13	The Effects of Conversational Partner Familiarity in Deaf Signers <i>Amanda C. Davis and Mary Lee A. Jensvold</i>	235
Chapter 14	Using Written English in the American Sign Language Classroom <i>Jason Listman and Kalyna Sytch</i>	249

VOLUME 2

Chapter 15	Children as Little Linguists <i>Hicham Khabbache, Ali Assad Watfa, Anna Siri and Nicola Luigi Bragazzi</i>	263
Chapter 16	Verbal Grammar Correlation Index (VGCI) as a Tool of Comparative Linguistics <i>Alexander Akulov</i>	295
Chapter 17	Academic Literacy Adaptation in the International Graduate Students' Use of Lexical Bundles through Corpus Research <i>Eunjeong Park</i>	341

Chapter 18	Multisemiotic Analysis of Orthodox Patriarchs' Photographs: Cross-Cultural (Indian and Russian) Differences in Interpretation of Interactive Meanings <i>Mariia Rubtcova, Oleg Pavenkov and Julia Varlamova</i>	351
Chapter 19	Multiple Types of "The Good" in Hryhorii Skovoroda's Philosophical Discourse: <i>Dobro vs Blaho</i> <i>Larysa M. Dovga</i>	389
Chapter 20	Morphological versus Phonological Awareness in Czech Readers: A Case of Transparent Orthography <i>Jiri Jost, Helena Havlisova, Ludmila Zemkova and Zuzana Bilkova</i>	417
Chapter 21	The Relationship between Vocabulary and Reading Development <i>Irene Cadime</i>	435
Chapter 22	Incidental Vocabulary Learning through Negotiation for Meaning in Synchronous Computer-Mediated Communication <i>Sarah H. J. Liu</i>	449

VOLUME 3

Chapter 23	Effectiveness of Voice Therapy in Vocal Fold Nodules <i>Victor Valadez and Rosa Isela Magallanes</i>	463
Chapter 24	Speech and Language Pathology Interventions in Critical Care: A Retrospective View <i>Kathleen V. Roeder</i>	469
Chapter 25	Speech Sound Disorders Protocol Guide for Speech and Language Pathologists <i>Marisa Lousada and Margarida Ramalho</i>	475
Chapter 26	A Play Toolkit Used in Early Language Intervention <i>Kristine Rutkowski</i>	487
Chapter 27	The Impact of Protracted Phonological Disorders on Literacy Outcomes in Children: A Meta-Analysis <i>Glenda Kelly Mason and Barbara May Bernhardt</i>	499
Chapter 28	Clinical Outcomes in Medical Speech-Language Pathology <i>Richard M. Merson and Michael I. Rolnick</i>	551
Chapter 29	Velopharyngeal Function and Speech: Analysis of Surgical Outcome in Young Adults with Repaired Cleft Palate and Residual Velopharyngeal Insufficiency <i>Mirta Palomares, Drina Alvarez, Carlos Giugliano and Carolina Villena</i>	571
Chapter 30	Strategies for Treating Phonologic Disorder in Children with Cleft Palate <i>Maria C. Pamplona and Santiago Morales</i>	583

Chapter 31	Phonetic and Phonological Difficulties Associated with Expressive Language Impairment in Young Children: A Review of the Literature <i>Dilara Deniz Can and Eileen Brudish</i>	599
Chapter 32	Coarticulation <i>Veno Volenec</i>	633
Chapter 33	Speech Intervention for Correcting Compensatory Articulation in Children with Cleft Palate <i>Pablo Antonio Ysunza</i>	663

VOLUME 4

Chapter 34	A Review of Major Strands in Discourse Analysis in Language Teaching <i>Dogan Yuksel and Banu Inan</i>	677
Chapter 35	Issues about Conducting Discourse Analysis Research <i>Dogan Yuksel and İhsan Unaldi</i>	687
Chapter 36	Corpus Linguistics and Discourse Studies <i>Ihsan Unaldi</i>	695
Chapter 37	Action Research: The Effects of Teacher Oral Discourse on EFL Writing <i>Wayne Trotman</i>	709
Chapter 38	Discourse of Readers' Blogs in College-Level ESL Classrooms <i>Justin E. Jernigan and Yingliang Liu</i>	719
Chapter 39	A Discourse Analysis on the Mitigation Language Used in the Supervision of Colleagues <i>İrfan Kuran</i>	737
Chapter 40	A Comparison of the Corrective Feedback Patterns of Native and Non-Native Speaking Teachers of English: Turkish and American ELT Settings <i>Banu Inan</i>	749
Chapter 41	Uptake and Audio Recordings: Exploring Learners' Responses to Corrective Feedback <i>Megan Calvert</i>	761
Chapter 42	Writing and Revision with Coded and Uncoded Feedback <i>Patricia Tehan</i>	781
Chapter 43	Living in a Multilingual World: Latest Trends in Language Learning via a Wide Array of Educational Technology Tools <i>Ana Niño</i>	793

Chapter 44	Peer-to-Peer Foreign Language E-Learning Stimulated by Gamification and Virality <i>Ilya V. Osipov, Alex A. Volinsky and Anna Y. Prasikova</i>	801
Chapter 45	Secondary EFL Learners' Extracurricular L2 Contact and Their Self-Beliefs Concerning Oral Narrative Competencies: Analyzing Relations among Constructs – Clarifying the Role of Language Proficiency and Gender <i>Günter Faber</i>	849
Chapter 46	A Learner's Foreign Language Self-Concept and Anxiety about Speaking the Language <i>Reiko Yoshida</i>	891
Chapter 47	Do 'Resourceful' Methodologies Really Work in 'Under-Resourced' Contexts? <i>Eric Enongene Ekembe</i>	913
Chapter 48	'From Michelangelo to Picasso': Implementing the CLIL Approach in a Foreign Language Project <i>Evangelia Anagnostou, Eleni Griva and Kostas Kasvikis</i>	933
Chapter 49	New Developments in Lexical Inferencing and Incidental Vocabulary Acquisition in Foreign Language Learning <i>Feifei Han</i>	953
Chapter 50	New Literacies: Current Perspectives on Teaching English as a Foreign Language <i>Andréa Machado de Almeida Mattos</i>	967

VOLUME 5

Chapter 51	Neuroimaging and Aphasiology in the 21 st Century: EEG and MEG Studies on Language Processing in Aphasia Since the Year 2000 <i>Marie Pourquié and Phaedra Royle</i>	989
Chapter 52	Language Processing in Children with Specific Language Impairment: A Review of Event-Related Potential Studies <i>Phaedra Royle and Emilie Courteau</i>	1013
Chapter 53	Analyzing Language Use of Learners with Learning Difficulties and Disabilities with Regard to Challenging Behavior <i>Larry L. Lee</i>	1037
Chapter 54	Inspection Time for Verbal Stimuli: Letter Detection, Identification, and Discrimination Speed <i>Tabitha W. Payne and Gaither Smith</i>	1055
Chapter 55	Visual Recognition of Chinese Compound Words is a Serial Process <i>John Xuexin Zhang</i>	1069

Chapter 56	Learner and Teacher Characteristics <i>Firdevs Karahan</i>	1075
Chapter 57	Lesson Planning in Language Teaching <i>Banu Inan Karagul</i>	1091
Chapter 58	Microteaching in ELT <i>Dogan Yuksel</i>	1103
Chapter 59	Teaching Speaking in EFL Classes <i>Çağlayan Erdönmez</i>	1113
Chapter 60	Teaching Listening <i>Aylin Köyalan</i>	1139
Chapter 61	Intelligibility in Pronunciation Teaching: A Study of Accented Speech of Turkish Speakers of English <i>İrfan Kuran</i>	1153
Chapter 62	Vocabulary Instruction in EFL Classes <i>Ihsan Unaldi</i>	1165
Chapter 63	Teaching Writing <i>Tülin Yildirim</i>	1187
Chapter 64	Teaching Reading in EFL Classes <i>Mehmet Bardakçı and Kadriye Dilek Akpınar</i>	1209
Chapter 65	Teaching Grammar <i>Banu Inan Karagul and Dogan Yuksel</i>	1233
Chapter 66	Integrated Skills in Language Teaching <i>Andreea Nicolaescu</i>	1243
Chapter 67	Using Literature to Teach Language Skills <i>Aşkın Haluk Yildirim</i>	1255
Chapter 68	Using Tasks in Language Teaching <i>Gokce Bayraktar</i>	1277

VOLUME 6

Chapter 69	Cognitive Linguistics in the Year 2010 <i>Laura A. Janda</i>	1297
Chapter 70	Conceptualization, Symbolization, and Grammar <i>Ronald W. Langacker</i>	1327
Chapter 71	Conceptual Combination: Models, Theories and Controversies <i>Bing Ran and P. Robert Duimering</i>	1361
Chapter 72	WATER Networks, the Chinese Radical, and Beyond <i>Rong Chen</i>	1387

Chapter 73	Construal Operations of the English Progressive Construction <i>Kim Ebensgaard Jensen</i>	1413
Chapter 74	The Pronoun <i>It</i> : A Study in Cognitive Grammar <i>Zeki Hamawand</i>	1439
Chapter 75	Iconicity, Subjectification and Dominion in Portuguese Concessive Clauses: Conceptual Differences between Concessive Clauses Introduced by <i>Apesar De</i> and <i>Embora</i> <i>Rainer Vesterinen</i>	1465
Chapter 76	<i>Seem</i> : Evidential, Epistemic, or What Else? A Study in Cognitive Semantics <i>Günther Lampert</i>	1489
Chapter 77	Manner of Motion: A Privileged Dimension of German Expressions <i>Sabine De Knop and Françoise Gallez</i>	1515
Chapter 78	Metaphorical Motion in Linguistic Context: Processing in English and Spanish <i>Jill Hohenstein</i>	1533
Chapter 79	Culture in Embodiment: Evidence from Conceptual Metaphors/Metonymies of Anger in Akan and English <i>Gladys Nyarko Ansah</i>	1553
Chapter 80	Attentional Profiles of Parenthetical Constructions: Some Thoughts on a Cognitive-Semantic Analysis of Written Language <i>Martina Lampert</i>	1573
Chapter 81	The Socially Embedded and Dynamically Embodied Nature of Metonymy's Prototypicality <i>Kent Hill</i>	1599
Chapter 82	Perception of Emotional Interjections <i>Åsa Abelin</i>	1619
Chapter 83	Creative Cognition: A 'Wave Method' Analysis of Franz Kafka's 'Metamorphosis' <i>Matthias Krug</i>	1637
Chapter 84	Approximative Spaces and the Tolerance Threshold in Communication <i>Barbara Lewandowska-Tomaszczyk</i>	1659
Chapter 85	When My Eyes Are on You, Do You Touch My Eyes? A Reclassification of Metaphors Mapping from Physical Contact to Perception <i>Karen Sullivan and Wenying Jiang</i>	1679

Index		1875

PREFACE

This 7 volume encyclopedia set presents important research on linguistics. Some of the topics discussed herein include speech and language disorders, language development, American Sign Language, voice therapy, and aphasia.

Chapter 1 - Verbs are the best lexical items to verify the effects of motor learning in language processing. However, compared to nouns, this category has received less attention in studies about lexical disturbances in neurological diseases. Difficulties in verb/action processing have been found in patients with Parkinson's disease, suggesting that frontoestriatal and subcortical areas contribute to the semantic processing of verbs. This finding highlights the possibility of verifying the assumptions of the Embodied Cognition (EC). According to this theory, language processing of action verbs would engage areas involved in planning and execution of the actions represented by those verbs in the motor cortex. The literature in this field has pointed to conflicting results and action/verb cerebral representation, and its impact in language difficulties in Parkinson's disease have been intensively debated. These controversies may be studied in terms of the multilevel model that predicts that the design of the task will require differential access to the motor features of the verb meaning and that areas related to visual perception, particularly the lateral posterior temporal cortex play a role in semantic processing. The type of task and psycholinguistic variables need to be taken into account since they can measure different levels of semantic processing. In addition, in order to check EC assumptions, studies must contrast distinct types of verbs, for instance action vs. emotional/psychological; biological vs. non-biological; verbs requiring and not requiring tools. Another semantic feature of concern is specificity. Kim and Thompson (2004) distinguish light and heavy verbs and discuss their different speed of deterioration in neurodegenerative diseases. Considering this panorama, this chapter will present, a summary of the different approaches about action/verbs semantics, current debates about verb neural representation and an analysis of the evaluation directed to patients with Parkinson's disease. A PubMed and Scopus search was conducted in December/2014 using the terms "action verb" OR "verb" OR "verbs" AND "Parkinson's disease" with no time restriction. The authors retrieved 35 studies and selected 22 for analysis, excluding reviews and studies not related to action/verb semantics in PD. The methodology and findings of those 22 studies were analyzed and contrasted with theories that explain the neural representation of action/verb semantics, in particular the multilevel model and Embodied Cognition accounts. The challenge for new studies is to identify those semantic properties,

understand how they are related to cortical processing and develop suitable tools to analyze these features in different profiles of Parkinson's disease.

Chapter 2 - This chapter aims to acquaint the reader with the current debate on the prevalence of oral and written linguistic difficulties as a precursor of Specific Learning Difficulties (SLD). The barrier created by scientific literature in terms of the diversity of terminology regarding the definition of these pathologies – which clearly reflects the interests of various fields – has given rise to multiple nosological classifications to define the same disorder, which has in turn hampered a diagnostic classification. This situation, in addition to a historical constant of disagreement regarding the definition and identification of SLD, has led to the identification of SLD in a child who has shown no signs of intellectual, sensory, physical or perceptive impairment in their learning that would keep them from reaching the objectives for the course or corresponding academic year in which they are enrolled.

Some factors that influence the appearance of SLD are *Speech Delays* (SD) and/or *Oral Language Delay* (OLD), as well as *Written Language Delay* (WLD), especially reading difficulties, as shown in epidemiological studies indicating a high prevalence. Likewise, delays in different linguistic components (semantic and/or syntactic) also significantly affect the comprehension and assimilation of text content, leading to learning difficulties. Therefore, the authors understand the need for a more comprehensive study of the relationship between delayed linguistic components and reading comprehension and fluency, given the high rates of prevalence during the first years of school and the possible origin of academic disabilities among students with LD.

In this respect, knowledge of the prevalence of linguistic difficulties during early childhood can facilitate the early detection and prevention of LD in the student population. This is due to the fact that the majority of language and communication problems will appear in the classroom environment, which incorporates the demands and implications of the teaching and learning process.

A recent study on the prevalence of language, speaking, voice and communication pathologies observed that, among the epidemiological profile of different pathologies present until adolescence, WLLD, OLD and SD constitute the greatest percentage as compared to other linguistic pathologies, and that gender differences were also present.

From this perspective, teachers are considered the most critical and responsible factor in the educational changes and improvements for the child. Nevertheless, teachers perceive certain limitations in their ability to intervene with these students within the classroom. The authors would therefore like to provide teachers with key epidemiological tools using the “*Precede-Proceed Model*” as an early detection and prevention device for Specific Learning Difficulties (SLD).

Chapter 3 - Depending on how broadly or narrowly defined, language can include multiple processes which go well beyond speech production and comprehension. Though typical language development is a stepping stone process based on its component parts, such as phonology, morphology, syntax, and pragmatics, it quickly branches into a vehicle for broad communication, including gestures, social and affective orientation toward others, and the facilitation of our learning and thinking skills. Considering its involvement in so much of what we do, language has been proven to be an extremely complex and diffusely distributed function in the human brain. Considerable research shows that individual language process development proceeds in a very predictable manner and parallels specific areas of brain development. Research appears to support a critical period hypothesis during which the brain

is maximally sensitive to specific types of language stimulation required for acquisition of skills associated with the next developmental phase. Thus, it seems clear that both genetics and environmental factors are important. Delays in the development of language skills and acquired deviations from normal language functioning can often be diagnostic of a pathological process. Given the great specificity in knowledge regarding the many neuroanatomical structures involved in language, language symptoms can be reasonably well localized in the brain. When language development deviates from the normal timeline, clinical interventions are often essential. Most evidence suggests that earlier intervention is more efficient. There are many creative and evidenced based treatments for language delays; however, depending on the severity and duration of the delay, the amount of treatment needed and the prognosis can vary widely. In cases where a delay is extreme there are often other noted cognitive and social deficits. Some speculate that delayed language could even plausibly limit the development of many other cognitive skills. This chapter discusses the more current broad conceptualization of language development and many of the evidence-based treatments. These include behavioral interventions such as Discrete Trial Training, as well as other methods: parent mediated, narrative mediated, social communication interventions, and sensory based interventions.

Chapter 4 - Cohen and coworkers were the first to demonstrate the presence of significant difficulties in language development and/or of the evolutive trajectory of this function in subjects evaluated in their adolescence for serious psychopathology. Subsequent longitudinal studies showed that children with language and communication disorders are at risk of having social, behavioral and emotional difficulties in adolescence and adult age.

A number of different mechanisms can be invoked to explain this association. First, language is a powerful tool for processing difficulties both in the relational contest and related to the so-called “social problem solving”. Others believe that the defect in mentalization associated with a frailty of executive functions might produce a decline of language skills in individuals predisposed to develop a psychopathological disorder. Still others point out that it is possible that the deficits in language make psychopathological problems that otherwise would have remained sub-threshold more evident and serious, as they reduce the relational exchanges. Finally, it has been hypothesized that there may be other mechanisms common to both the difficulty of the language and the psychopathological disorders, in terms of both genetic aspects and neurocognitive functions (e.g. working memory deficits).

In any case, it is evident that an atypical functioning of a given subject in the field of language is a relevant factor for the treatment, especially when the treatment method largely uses the word to induce a change in mental functioning (as in most psychotherapies).

Chapter 5 - This chapter examines the role played by intercultural nonverbal communication competence of Australian university staff members working in a culturally diverse setting and its impact on the management of intercultural working relationships with the students. The discussion starts with a critical review of relevant nonverbal communication theories (e.g., paralinguistics, proxemics, and kinesics). Then it focuses on various body language challenges academic and professional staff members working in Australian universities face on a daily basis while facilitating and working with students who come from diverse linguistic and cultural backgrounds. The body language facing academic staff members inside classroom is challenging due to intricate intercultural differences and potential intercultural misunderstanding. It is argued that an issue common to both academic and professional staff members is that some of them may have insufficient

intercultural nonverbal communication competence and few have received intercultural nonverbal communication training relevant to their work roles though their verbal communication skills are sound. It is believed that competent intercultural nonverbal communication is crucial and indispensable for both academic and professional staff members working in Australian university context because Australian higher education sector has such a linguistically and culturally diverse environment and it has an internationally high-stake profile with some universities having as many as 20% or more international students from different cultures. This has created pedagogical implications that students are likely to achieve better learning outcomes and have better learning experience when their teachers are able to demonstrate their intercultural nonverbal communication competence. It is the same case with professional staff members whose competent intercultural nonverbal communication skills can accommodate students' various needs (e.g., psychological, emotional, and social). In a word, Australian university staff members' good intercultural understanding (language and cultural knowledge about international students, so-called clients) and effective nonverbal communication skills will contribute to presenting their universities a positive public image, internationalizing Australian higher education industry and making it competitive globally.

Chapter 6 - Having in mind the importance of segmental duration from a perceptive point of view, a specialized module for modeling segmental duration in natural speech is a very important component of a text-to-speech (TTS) system in order to produce high quality synthetic speech which sounds natural. In this study various machine learning techniques were applied for phone duration modeling of the Serbian language. In this chapter different phone duration prediction models for the Serbian language using linear regression, tree-based algorithms and meta-learning algorithms such as additive regression, bagging and stacking algorithm are presented. Phone duration models have been developed for the full phoneme set of the Serbian language as well as for vowels and consonants separately. A large speech corpus and a feature set of 21 parameters describing phones and their contexts were used for the prediction of segmental duration. Phone duration modeling is based on attributes such as the current segment identity, preceding and following segment types, manner of articulation (for consonants) and voicing of neighboring phones, lexical stress, part-of-speech, word length, the position of the segment in the syllable, the position of the syllable in a word, the position of a word in a phrase, phrase break level, etc. These features have been extracted from the large speech database for the Serbian language. The phone duration model obtained using additive regression method outperformed the other models developed for the Serbian language within this study using different modeling techniques. This model obtained for the full phoneme set outperforms the second best model by approximately 1.3% and 1% in terms of the relative reduction of the root-mean-squared error and the mean absolute error, respectively.

Chapter 7 – Purpose: Inferential comprehension is an important aspect of language development in the early years and is strongly associated with future academic success. Yet, this language ability has not been extensively documented in young children with SLI. Information in that regard would be helpful in guiding assessment and intervention in speech-language pathology. This study aims to collect data on inferential abilities of 5-year-old children with SLI.

Methods: Sixty-four children, distributed in three groups, participated in the study: 16 children with SLI were compared to 26 age-matched and 22 language-matched typically

developing children. Inferential abilities were examined with pre-determined questions inserted into a dialogic reading task. The performance of the three groups of children was compared according to the inference types and the quality of responses provided.

Results: Children with SLI obtained similar results to the younger language-matched group and weaker results than the age-matched group. Significant differences among the three groups were observed for both inference types and quality of responses.

Conclusions: This study provides new information about the inferential abilities of children with SLI and typically developing children aged 4 to 5 in the context of dialogic reading. The results offer some foundation for planning assessment and intervention in the area of inferential comprehension with young children.

Chapter 8 - This chapter describes a speech and text translator from Spanish into Spanish Sign Language, trying to solve some of the problems that deaf people find when they try to access and attend to specific training courses. The application uses the voice as input for translation, but it also translates text from PowerPoint slides used by the teacher to explain the lesson concepts. In addition to the translator system, a virtual avatar has been created and integrated in the final application to visually represent the signs translation. A set of real-time avatar animations representing the signs are used, with individual words and common used phrases in the training environment. The process to create, adapt and reproduce the movements and mix them in real time is described. The tool is based on a client/server architecture where teacher and deaf students have their own application to help both in teaching and learning during a class session, also facilitating the communication between them using a chat. The system can be used in courses where deaf and hearing people are sharing the same material and classroom, so deaf people can attend and follow the class without problems, improving the integration of this group of people to specific academic areas. The tool has been tested to obtain direct information with a group of deaf people from the Deaf Association of Seville.

Chapter 9 - The authors evaluated the perceived communication ability of 25 individuals with chronic traumatic brain injury (TBI) and 25 age-sex-education matched normal controls using an open questions interview format. Each participant completed the interview, which consisted of 21 open questions such as ‘What kind of people are your parents?’ as well as other linguistic and cognitive tests. Using audio recorded versions of the interviews, the authors rated their answers using the 27 subscales of the La Trobe Communication Questionnaire (LCQ), and evaluated the relationships between LCQ scoring and the other tests. There was a significant difference between participants with and without TBI for 18 of the 27 subscales of the LCQ. As for the 4 factors (Initiation/Conversational flow, Disinhibition/Impulsivity, Conversational Effectiveness, and Partner Sensitivity), the total score for each differed between the 2 groups. Furthermore, LCQ Factor 3 (Conversational Effectiveness) showed a significant correlation with duration of loss of consciousness. No measurements of linguistic and cognitive ability showed a significant relationship with LCQ factor scores. The authors’ findings suggest that communication difficulties can persist for years after injury, which may be relatively independent from other cognitive abilities.

Chapter 10 - The study of nonverbal behavior is important in objectifying and verifying the diagnosis of mental disorders. Also it is important in establishing correct diagnosis of affective disorders (anxiety and depression) in patients with type 1 diabetes using clinical and ethological methods. Ethological analysis of the behavior of children and adolescents with diabetes was conducted using adapted to the objectives of the study “Glossary of nonverbal

human behavior”, which includes basic units, simple and complex forms of behavior, as well as their dynamics. Formalization of the severity of behavioral symptoms was carried out in accordance with the scale of human ethological features (Human Ethological Signs Scale, HESS), which provides a 7-point score for ethological expression. The authors have revealed and ranged several nonverbal patterns recorded with a frequency of more than 90%, which were of particular importance for ethological verification of anxiety in children and adolescents suffering from diabetes. The authors’ results show that ethological analysis of nonverbal behavior in children and adolescents with type 1 diabetes significantly increases the information content of the clinical examination, contributes to objectification and verification of clinical and psychopathological data concerning the presence and severity of affective disorders caused by diabetes and allows one to confidently discriminate between depressive and anxiety disorders in the absence or even loss of verbal contact with the patient.

Chapter 11 - Religious beliefs can be expressed in distinct language varieties – one such variety is the language of the sermon which Crystal and Davy (1969) say, “Has more in common, stylistically with other forms of public speaking.” Being a form of moral statement aimed at dictating a certain kind of behavior through such strategies as stories, or examples, a sermon’s manner of presentation is formal. This chapter focuses on how content is structured in formal KSL discourse – a sermon. It focuses on grammatical cohesion. Grammatical cohesion is about how content is structured through textual features that link episodes together in discourse. In discourse, there are elements that are not part of the content but they help in guiding the reader/listener to interpret information. The flow of the topic can therefore be understood through guidance from structural organization, or through cohesive devices. The structuring of content in discourse through the use of structural devices or linguistic features that mark transition help in establishing cohesion. This chapter is concerned with how cohesion is established in a KSL sermon through reference, substitution, ellipsis, discourse markers and conjunctions.

Chapter 12 - A novel computer-based adaptive test of ASL ability known as the American Sign Language Discrimination Test (ASL-DT) recently has been developed at the Rochester Institute of Technology's National Technical Institute for the Deaf (RIT/NTID). The ASL-DT is a measure of learners’ sign recognition ability. Specifically, the test measures the ability to discriminate phonological and morphophonological contrasts (minimal pairs) in ASL. Both the item content and test administration methodology differ substantially from procedures currently used for the assessment of second language (L2) learners’ sign language abilities. Using a paired comparison discrimination task and Rasch analysis to model item difficulty and person ability, the ASL-DT provides an objective, valid and reliable measure of ASL skills that can serve as a proxy measure of ASL proficiency.

In this chapter, the authors report the results of a study designed to enlarge the ASL-DT item pool to expand the effectiveness of the test across the full range of L2 learners’ ASL abilities. A set of 280 items was administered to a sample of 178 adults having ASL proficiency levels extending from beginners to native signers. Forty-eight of the items were used in previous research, and 232 items were newly developed.

Goals of the study included providing additional evidence of the test’s reliability and validity, as well as providing preliminary evidence of the effectiveness of the adaptive test. The chapter builds upon previous work indicating that evaluation of learners’ ability to recognize linguistic contrasts can provide useful information about their acquisition of ASL as well as previous work indicating that the ASL-DT may provide a useful complement to

measures such as the Sign Language Proficiency Interview (SLPI) and the American Sign Language Proficiency Interview (ASLPI) in comprehensive sign language assessment programs.

Chapter 13 - The way in which an individual communicates changes based on various conversational aspects. Speakers adapt the form and content of their messages based on their judgments of what the listener knows and needs to know. Familiarity of a conversational partner affects verbal and nonverbal communicative behaviors. This is change in register, or language style, and is indicative of the ability to adapt to the listener. This study examined the effects of familiarity and the use of American Sign Language in deaf humans' conversational behaviors. Participants were deaf adults either living at or clients of a deaf assisted living facility. Participants were videotaped interacting with a conversational partner for 4 min each while playing a game. There were two conditions of trials: the partner was familiar versus unfamiliar to the participant. Two signing behaviors were measured: average duration of sign and reiteration of sign. All participants' duration of sign and reiteration of sign were significantly longer when interacting with an unfamiliar conversational partner. This research provides evidence for the linguistic aspects of ASL that are like spoken languages. These results add to research showing difference in conversational register in response to different types of partners.

Chapter 14 - In the field of American Sign Language (ASL) pedagogy, the most popular teaching method seems to be the Direct Experience Method (DEM). DEM encourages teachers to use ASL with the support of pictures, mime-pantomime, objects, and/or scenarios to teach vocabulary, language structure, and concept rules. Advocates of DEM discourage using English as a learning tool in the classroom. Studies in the field of second-language acquisition (SLA) show mixed results; some claim that only the target language should be used in the classroom while others argue that some use of the first language (L1) in the second language (L2) classroom helps students learn better. This study compared DEM with a modified DEM that includes written English as a learning tool to see which approach is more effective. The results suggested that the participants taught through DEM with written English support outperform those who are taught strictly with DEM and no written English. This study can help teachers understand the potential benefits of using minimal amounts of a student's native language in L2 classrooms. Limitations and recommendations for future studies are also highlighted in this chapter.

Chapter 15 - Language represents an intriguing and challenging topic, having fascinated mankind since its dawn. In the current study, the authors' aim is to show the shortcomings of classical single-factor/unilateral theories of word learning, lexical acquisition, and language development, that generally tend to restrict these processes to single causes, constraints, factors or principles. Such theories imply a unilateral, linear growth pathway of language learning, acquisition, and development. Participants were 128 Moroccan children, 71 boys and 57 girls, aged between 4 and 12 years, all belonging to the social middle class. They lived in Taza city, capital of Taza province, a city in northern Morocco, 120 kilometers east of Fez, with a population of approximately 300,000 citizens, and surrounded by the Rif and Middle Atlas mountains. They were exposed to the two tasks, namely to the task of distinguishing between the appearance and the reality of a word and to the "False Belief Task on Word-Concept". The authors borrowed both tasks from the theory of mind and tried to adapt them to the field of linguistics, aiming at discovering the child's ability to distinguish between the *signifier* as an acoustic-linguistic reality, the *signified* as a

mental entity and the *reference* as a physical/material entity. Findings of the current study support the pluralistic mentalist word theory.

Chapter 16 - Method of comparative linguistics based on comparison of lexis allows making different conclusions about the genetic classification of the same language. When different conclusions are based on the same methodology it is the best evidence that such methodology (comparison of lexis) is irrelevant. Language isn't a heap of lexemes, but is ordered pair $\langle A; \Omega \rangle$ where A is set of grammatical meanings and Ω is set of positional distributions defined upon A . On the base of such understanding of language was elaborated Verbal Grammar Correlation Index (VGCI). The main idea of VGCI is simple: more closely related languages have more alike sets of grammatical meanings and their common meanings are distributed in more alike positions, so the index of correlation of more closely related languages is higher. VGCI is the direct comparison of languages which exist/existed in reality. VGCI works with pure structures (it doesn't use any reconstructions or comparison of material exponents). Tests of VGCI on the material of firmly assembled stocks (Austronesian; Indo-European; Sino-Tibetan) showed the following: if value of VGCI is about 0.4 or higher it means that compared languages are related; if value of VGCI is about 0.3 or lower it means that compared languages aren't related. With use of VGCI have been found relatives of Ainu language (Great Andamanese language and Sino-Tibetan stock) and has been proven relatedness of Austronesian and Austroasiatic stocks. VGCI can be extremely useful in the fields of genetic classifications of indigenous languages of the Americas, Papuan languages and Australian Aboriginal languages.

Chapter 17 - More and more international students come to the United States to study in higher education. Due to the increasing number of the population, international students are considered crucial for the economic and social impact on academia in the U.S. For instance, they have contributed more than 30.8 billion dollars to the economic vigor of the U.S. higher institutions and their communities. However, international students' adaptation may not be successful due to several reasons. One of them would be their language proficiency—in particular, productive language skills: writing and speaking. In the academic setting, many international students struggle with their written assignments in English. Acknowledging the international students' challenge of academic writing in English, this study investigated international graduate students' academic literacy adaptation via corpus research. The use of lexical bundles was examined as one of the academic literacy adaptation indicators in this corpus-based study. The results revealed that the students did not use stance lexical bundles, indicating that they may not express their own voices in critical reviews. Rather, they tend to write carefully to reflect the original articles. This study suggests that we should view international students' academic literacy adaptation with larger corpus data. Further implications of the findings are discussed.

Chapter 18 - The chapter investigates the role of the implementation of the multisemiotic theory through the analysis of the Orthodox Patriarchs' photographs. The research is based on the multisemiotic theory by Kress and van Leeuwen and supports the view that semiotic codes are used in specific historical, cultural and institutional contexts. It is customary for people to communicate the meaning referring to various codes, depending on the contexts, as codes are not only planned, taught, justified, but also criticized. The authors of this chapter make an attempt to prove the hypothesis that Russian and Indian respondents code similar photos differently due to their cultural/ideological backgrounds. According to Kress and van Leeuwen, pictures are images that convey an interactive meaning. Thus, the main focus of the

research is on the image viewer interaction. The present study examines the data obtained from 526 official photographs of the Patriarchs and consists of several stages. At the first stage two groups of coders (Indian and Russian) were created. The selected groups were provided to code the collected corpus of photos (in total 526 photographs) autonomously. In case of discrepancies between the coding images, the agreement was terminated by two national coders collaboratively. At the second stage, the semi-structural interviews with the coders were conducted. The interviews allowed to identify and reveal similarities and differences in photo perception. The results of the study show, that the multisemiotic theory can be entirely employed and serve as an effective tool in image analysis within different cultures through identifying the interpersonal (interactive) metafunction. As the research demonstrates limitations like small amount of studied samples and a low number of Indian participants' opinion provided in the Russian Federation, further research in India is recommended.

Chapter 19 - This chapter is dedicated to the formation of philosophical terminology in the history of Early-Modern Ukrainian culture. Two philosophical concepts—*dobro* and *blaho* (добро and благо)—are the focus here. Both are related to notions of good and wellbeing, but contextual nuances may affect their discrete meanings rather significantly. My main goal is to track the differences between them and discover the rationale behind them. The author consider the manner in which these two words functioned in the works by the prominent 18th century Ukrainian philosopher Hryhorii Skovoroda. My study is based on a close reading of thirteen of his colloquies. In the process, the author has also tackled the problem of translation posed by these complicated terms.

My study has led to the following conclusions: 1) Skovoroda uses the word *blaho* when discoursing about the Creator, the Sacral World, and reflections of the sacral in profane human life. In such contexts he uses *blaho* as a philosophical concept. 2) Skovoroda reserves the term *dobro* for the profane sphere, while describing things that are positive from a moral point of view. In such cases, the semantic field of the word is clearly defined, though it can hardly be called a philosophical term. 3) The common, conversational application of *dobro* does not have clearly defined boundaries and as such it does not represent a discrete concept. 4) When translating Skovoroda's works into other languages, it is desirable to select the closest equivalents of each term. For example, the Greek κάλλος (τὸ κάλλον) or τὸ εὖ and the English *Everyday Good* are good analogs for *dobro*. On the other hand, the Greek τὸ ἀγαθόν and the English *The Highest Good* or *The Ultimate Good* closely render *blaho*.

Chapter 20 - The aim was to investigate the relationship between morphological awareness and reading in a language environment which is phonologically transparent and morphologically challenging, i.e., the Czech language environment. The sample consisted of 171 typically achieving elementary school students (3rd to 6th graders). Morphological awareness and phonological awareness both had comparable influence on reading across all age levels, from the lowest (3rd graders) to the highest (6th graders). Morphological awareness affected reading speed and accuracy more than phonological awareness. Paradoxically, morphological awareness affected reading comprehension less than phonological awareness – authors interpreted this to be due to superficial reading style which manifested itself regardless of student age, gender or IQ. Implications for improvement of reading were discussed.

Chapter 21 - Research has indicated that vocabulary depth and breadth are strongly correlated with reading comprehension and, consequently, with academic achievement.

Recent research has demonstrated that vocabulary can even predict achievement up to 10 years later. Some theoretical models, such as the simple view of reading or the multicomponent view of reading have received extensive empirical support and provided a clear insight into the relationship between reading comprehension and other linguistic variables, including vocabulary. In the context of these frameworks, studies have explored if vocabulary has a direct effect on reading comprehension or if the relationship between both variables is mediated by word reading and listening comprehension. The results generally seem to support a mediation effect; however, more studies are needed in different orthographies and grade levels. Additionally, results of other studies have indicated the existence of reciprocal relationships between the development of vocabulary and different reading abilities, as well as between the development of vocabulary and the comprehension of oral language. The implications of these findings for the design of interventions and for the planning of reading instruction are discussed.

Chapter 22 - In the past few decades much research attention has been given to determining the effects of incidental vocabulary learning through negotiation for meaning on second or foreign language (L2/FL) vocabulary gains in a face-to-face (F2F) environment since vocabulary knowledge in L2 or FL is considered an important skill in order to have effective communication skills or good academic performance. In this line of inquiry, the nature of technology- or computer-mediated communication makes enhanced incidental learning feasible. This article aims to discuss relevant underlying theories and review previous empirical studies on language learning in both F2F and synchronous computer-mediated communication (SCMC).

Chapter 23 - Vocal fold nodules are a functional voice disorder associated with voice misuse and abuse. They are benign masses, typically located on the membranous aspect of the vocal fold. Voice therapy is a process that aims to bring voice to a level of fitness that can supply occupational, emotional and social needs, knowing that not all patients will achieve a normal voice. Voice training usually consists of a combination of “direct” and “indirect” treatment techniques. Direct techniques focus on the underlying physiological changes needed to improve an individual’s technique in using the vocal system. These techniques are aimed to modify and/or improve vocal fold closure (adduction), respiratory patterns, resonance, pitch and articulatory tension. In contrast, indirect procedures concentrate on contributory and maintenance aspects of the voice disorder and may involve relaxation strategies, counselling and explanation of the normal anatomy and physiology of the vocal tract, explanation of the casual factors of voice disorders and voice care and conservation.

Chapter 24 - Speech and Language Pathology interventions in critical care purport to improve patient care and patient outcomes by addressing the risk for aspiration due to iatrogenic dysphagia related to tracheostomy tube placement, ventilator dependency and critical illness myopathy. Many Speech Pathology recommendations address NPO status, need for alternative feeding via Corpak tube and need for PEG tube placement. A retrospective analysis of 20 patients admitted to the various medical neurosurgical and surgical ICU’s analyzed patients from two groups: those who were kept NPO until a Speech and Language Pathologist assessed swallow function and those who had an oral diet assigned by the medical team without an initial formal Speech Pathology swallow assessment. Among the parameters investigated were LOS in the ICU, need for re-intubation, number of NPO status days, recommendation for Corpak tube or PEG tube and discharge status with respect to oral feeding, tube feeding and modified diet.

Chapter 25 - Children with speech sound disorders (SSD) dominate the caseloads of many speech and language pathologists (SLPs) and form a heterogeneous group. The clinical practice with children with SSD involves several methods and theoretical assumptions. Different procedures should be considered in the assessment of children with SSD, e.g., case history, single word test, stimulability, oral motor-speech, phonological analysis (linear and non-linear), phonological awareness, syllable/ word shapes, intelligibility. Also, a large number of intervention approaches are available for children with SSD, for example, minimal opposition contrast therapy, traditional articulation therapy, core vocabulary, cycles approach, phonological awareness. It has also been suggested that some intervention approaches are more effective for some SSD subgroups.

More recently SLPs are also encouraged to use the International Classification of Functioning, Disability and Health (ICF), or the International Classification of Functioning, Disability and Health Children and Youth Version (ICF-CY) in order to contemplate not only the speech disorders (body structures/ functions) but also its impact in person's activities and participation and the contextual factors (environmental and personal) that affect communication. As professional associations suggests ICF can help SLPs using a common terminology system by adaptation of many classifications that are already in use.

Since clinicians have limited time and access to analyze all of the relevant studies about assessment and intervention for children with SSD and incorporate ICF in their clinical practice, the authors intend with this chapter to guide them to implement best practice for children with SSD in terms of clinical process (since case history to intervention outcomes) and include ICF terminology in all process. Specifically the authors will present the *SSD protocol guide for SLPs*.

Chapter 26 - Special educators often promote young children's pretend play abilities with play intervention methods because of the observed relationship between play skills and cognitive, social, and language development. In a 1993 study, teachers reported that approximately 75% of children with language disorders need assistance with social play skills. However, in his 1997 review of research on the symbolic play skills of children with language disabilities, M. W. Casby discovered play abilities not to be very lacking in these children. Most importantly, their capabilities for using symbolic ideas in play may be similar to those of children without language disabilities, revealing "a symbolic *performance* deficit more so than a symbolic *competence* deficit. In pretend play, difficulties with language consistently get in the way of making play themes and roles explicit. Similarly, Guralnik found that children with mild language disabilities tend to progress like their peers in terms of play, steadily transitioning from solitary to parallel to social play, for example, but simply taking longer to do so.

There is a growing body of evidence supporting the role not only of language proficiency in pretend play but also of pretend play in the acquisition of language. Specifically, the use of a variety of props and objects, combining multiple roles and themes, and creating pretend scenarios provide the best opportunities for fostering language growth. Using clearly defined, measurable language goals, the speech-language pathologist (SLP) can promote language growth by working through a pretend play developmental hierarchy. Initially, realistic props not only expand vocabulary of common objects and their functions but also help children maintain their roles and remember their play scenario while acting out activities of daily living. As pretend play advances, props become more symbolic, often taking on more than one function during play (e.g., a box used as a boat can be flipped over to be used as a cave).

The SLP progressively introduces these open-ended and multi-functional items as a child's linguistic structures emerge and evolve so as to establish their relationships. Eventually, children will learn to make their own props (e.g., play dough can be shaped into a pizza). This chapter offers the SLP a play toolkit that implements a hierarchy of pretend play techniques to advance the linguistic competence of language-delayed preschoolers.

Chapter 27 - Background: The literature is equivocal on whether children with protracted phonological development (PPD) are at risk for literacy acquisition, making it challenging to provide relevant evidence-based phonological intervention. Differences in researchers' definitions of PPD have possibly contributed to the contradictory outcomes.

Purpose: The purpose of the meta-analysis was to determine the consistency of word-level literacy differences for children with and without PPD, and whether such differences are moderated by definitions of PPD.

Method: Eligible studies had measured at least one word-level literacy construct in school-aged children with and without PPD. Fifty-two evaluated papers generated 64 independent samples to examine: *Phonological awareness (PA; n = 20)*, *Word decoding (DEC; n = 17)*, *Fluency (FL; n = 4)*, *Nonword decoding (NWD; n = 9)* and *Spelling (SP; n = 14)*. Multiple regression analysis of a model that included all constructs was significant, $F(4,60) = 85.96, p < .001$ ($t = 5.71, p < .001$). Sample sizes allowed moderator testing for *PA*, *DEC*, *NWD*, and *SP*. A random effects model was used to compare *mean unbiased d* (weighted by the *inverse variance* and *Random Effects Variance Component*) on the *Q*-statistic ($p < .05$).

Results: For *unbiased Cohen's d*, *95% Confidence Intervals* and *95% Credibility Intervals* were significant for *PA* ($d = .85$), *NWD* ($d = .50$), and *SP* ($d = .84$), but not *DEC* ($d = .63$) and *FL* ($d = 3.04$). Cultural context was a significant moderator of *SP*, suggesting dialectical influences. In defining PPD, age at literacy evaluation, severity/sub-type and resolution of PPD significantly moderated *NWD* ($Q = 14.21$) and *SP* ($Q = 8.00$). Complexity of speech context, particularly inclusion of multisyllabic word (MSW) evaluations, was a significant moderator of *PA* ($Q = 4.85$), *DEC* ($Q = 4.14$) and *SP* ($Q = 5.66$). Differences between children with and without PPD were greater in initial phases of childhood literacy compared with later phases.

Conclusions: In both initial and later phases of childhood literacy, early spoken phonological intervention seemed relevant to mitigating differences between children with and without PPD, although results were limited by the number of studies examined. To define PPD, spoken MSW phonology appeared important; a theoretically grounded continuous metric could increase study power, whether or not categorical samples are available.

Chapter 28 - This chapter will report on a large patient population (est. 20,000 from 1992-2013) from the Beaumont Health System (Michigan) which had been tracked consecutively on two different clinical outcome programs since 1992. The population includes inpatients and outpatients treated at multiple hospital and rehabilitation centers. Adults and children with communication disorders were tracked utilizing a customized clinical outcome software program (The Beaumont Outcome Software System ©, BOSS) with a large clinician based staff. After ten years the Speech-Language Pathology Department, Beaumont Health System transferred their outcome program to the American Speech-Language Hearing Association's National Outcome Measurement System ©, NOMS). This chapter reports and compares the two clinical outcome systems (BOSS© and

NOMS©) and discusses how outcome data contributes to Speech-Language Pathology management.

Chapter 29 - The protocol for the evaluation and treatment of young adults with cleft palate at a Cleft Palate Center in Santiago, Chile is described. All the patients studied with this protocol were young adults present with residual velopharyngeal insufficiency (VPI) after palatal repair. All patients underwent a complete speech evaluation. Surgery for correcting VPI was planned individually in each case according to findings of videonasopharyngoscopy (VNP). All cases were operated on with a superiorly based pharyngeal flap. The surgical procedures were performed by the same surgeon in all cases. Surgical outcomes of velopharyngeal function (VPF) were analyzed with postoperative VNP and a speech evaluation. Patients with normal articulation before surgery showed adequate VPF one month after the pharyngeal flap was performed. None of these cases required Speech & Language Pathology (SLP) treatment. None of the patients with compensatory articulation disorder (CAD) preoperatively showed adequate VPF one month after the pharyngeal flap operation. All these cases required SLP treatment including biofeedback with VNP. After a six-month period of SLP treatment and biofeedback, sixty – three percent of these patients achieved similar results as the group of patients with normal articulation before surgery. After a follow-up period of 6 months, a total of 79% of the cases showed satisfactory results of VPF during speech. Most patients showed good compliance and motivation for treatment.

Chapter 30 - Children with cleft palate (CCP) may be at risk for articulation disorders. These articulation patterns are known as compensatory articulation disorder (CAD) and are generally regarded as compensatory behaviors secondary to velopharyngeal insufficiency (VPI). Some authors consider these behaviors as a phonologic disorder. Whole language principles consider that there is an interaction between the phonological rules and other language rule systems. An articulation problem is far more complex in nature than a phonetic analysis would suggest, and during intervention, phonologic information should not be separated from the other areas of language, such as pragmatics or syntax. Thus, within the same activity, several pieces of information about all areas of language, including phonologic information are provided. Scaffolding strategies can be useful for correcting placement and manner of articulation. Sometimes, it is difficult to know which strategy would be best option for a specific moment. Few authors have specified the expected time to apply each strategy in order to improve effectiveness. However, when studying the efficacy of these strategies for treating CAD in CCP, some result more adequate depending on the specific stage of speech development or severity of articulation impairment. In this chapter some scaffolding strategies for phonologic intervention will be described and some ideas for using them in communicative situations in relationship with higher organizational levels of language processing.

Chapter 31 - Specific Language Impairment (SLI) occurs in 6.3% of children, twice as much in males than females. The typical range of prevalence of SLI during the preschool/early school years is between 2% and 8% with an overall median prevalence of 5.95%. SLI involves delays or deficits in expressive or receptive language development, or both. In the case of the expressive language impairment (ELI), children's language is characterized by small vocabularies; short, incomplete sentences; and confusing or disorganized conversations. ELI may involve difficulties with the form of language (phonology, morphology, syntax), the content of language (semantics), and/or the function of language in communication (pragmatics).

Deficits in phonology may include difficulties with early speech sound production, and/or weak phonological awareness skills (i.e., rhyming, sound isolation, segmentation, and blending), resulting in struggles with reading and writing. Deficits in morphology and syntax may include late use of word combinations, shorter utterances in words with errors often occurring on verbs (especially verb endings, auxiliary verbs, and past tense marking of regular and irregular forms), function words, pronouns, plurals, and later-developing prefixes/suffixes with difficulties in reading and understanding the meaning of words. Impairments in semantics may include poor vocabulary use; word-finding difficulties; using synonyms/antonyms, multiple-meaning words, and figurative language (e.g., idioms, metaphors, proverbs, humor, poetic language); poor organization of narratives and expository discourse that impacts ability to convey intended meaning. Difficulties in pragmatics may include difficulty expressing ideas, feelings, and personal experiences or difficulty initiating/sustaining conversations.

The purpose of this chapter is to review the most relevant research published that informs the definition, identification, and treatment of expressive language impairment (ELI) in children ages 3 to 10 years, with a focus on phonetic and phonological interventions. Early identification and treatment of ELI is crucial for several reasons. First, the Common Core State Standards Initiative (2015) emphasizes the importance of oral language and learning to read and write. Grade-specific morphological awareness standards begin to appear as early as 1st grade, specifically in the areas of Language Knowledge, Vocabulary, and Reading Phonics/Word Recognition. Second, adequate phoneme awareness appears critical to speech production and early reading success for children with speech impairment.

Targeted areas of intervention for expressive language deficits (ages 3 to 10) include but are not limited to phonological interventions such as increasing consonant repertoire, decreasing the use of phonological processes (e.g., final consonant deletion, fronting), and enhancing phonological awareness skills (e.g., rhyming, blending, segmenting, and elision). Timely implementation of such interventions, wherever the existing language skills may be on the expressive communication continuum, will benefit children's short-term as well as long-term language, literacy, and social-emotional skills.

Chapter 32 - One of the central issues in contemporary phonetics is that of coarticulation. Speech segments do not and cannot occur isolated in real speech. As elements of a multisegmental utterance in continuous speech, all segments have neighbors which exert a certain degree of influence upon them. The vast array of articulatory adaptations that occurs as a result of the influence of one phonetic structure on another is what constitutes coarticulation in its broadest sense. Because of its ubiquitous nature in continuous speech, coarticulation has been and continues to be a central research area in experimental and theoretical articulatory phonetics. Naturally then, any integral theory or model of speech production, and to a lesser degree speech perception, must account for coarticulation. In this chapter the authors provide a general introduction to coarticulation, to the techniques used to measure it, and to the major theoretical and experimental contributions in explaining the nature and principles that govern it. Depending on the theoretical approach, the definition and scope of coarticulation may vary significantly, thus the authors aim to review and assess some of the more influential models of coarticulation, which constitute a fundamental part of contemporary phonetics. Theories and models of coarticulation also have significant consequences on phonological theory, especially the phonology-phonetics interface. Modelling coarticulation is central to understanding how the categorical, timeless and

context-independent units suggested by phonology and the gradual, dynamic and context-dependent characteristics of continuous speech are related to each other. Therefore, in this chapter the authors also explore the place of coarticulation in the phonology/phonetics dichotomy, relating coarticulation to what may in essence be viewed as its phonological counterpart – assimilation.

Chapter 33 - Velopharyngeal Insufficiency (VPI) is a disorder of resonance and speech which affect all individuals with cleft palate. VPI can occur with or without compensatory articulation errors. Several intervention methods have been reported for treating compensatory articulation errors in patients with cleft palate. Two of the most commonly used of these intervention modalities are a phonologic based intervention and a phonetic or articulatory intervention. Although both modalities have been reported as being effective, it seems that a phonologically based intervention can more readily enhance to carry over the adequate articulation placement into connected speech. The reason for this advantage is that phonology addresses not only the peripheral aspects of speech production but higher levels of linguistic organization. Thus, addressing compensatory articulation errors in a more linguistically based context, can usually be more effective for acquiring and using an adequate articulation placement during connected speech.

It is necessary to appropriately classify the severity of the compensatory articulation errors, with especial focus on the response to speech pathology intervention strategies. Also, the selection of phonologically based strategies to be used during the speech intervention, seem to enhance effectiveness of the specific strategies for correcting articulation placement.

This chapter addresses how an approach based on phonological principles can be a reliable method for the speech intervention in children with cleft palate and compensatory articulation errors. In this chapter, a categorically stratified scale for classifying compensatory articulation errors according to severity and response to therapy is described. Finally, some strategies for speech intervention which are more suitable for a phonological and linguistic intervention are presented. The chapter explains how is that selecting the strategies to be used during the intervention according to the severity of the articulation errors seem to increase their effectiveness.

Chapter 34 - This chapter reviews major perspectives towards discourse analysis in foreign and/or second language learning and teaching settings. Three major strands that have been examined are Critical Discourse Analysis, Interactionist Discourse Analysis and Sociocultural Discourse Analysis. Each perspective is reviewed by providing the major characteristics of the perspectives and some sample studies. One or two most current studies that are published in major journals of the authors' field have been added to the reviews as well.

Chapter 35 - The main aim of this chapter is to help novice researchers gain some insights about conducting a discourse analysis research study. The authors mostly refer their previous experiences and discuss some issues that might facilitate the research process. The authors have divided this section into three sections. The first section, before data collection, discusses some issues to be done prior to the data collection process. During data collection mainly deals with how to record the data and obtain any other necessary information. The final section focuses on topics such as data transcription, data indexing, data reduction, coding and interrater reliability. Illustrations and samples are given whenever necessary. The chapter also includes a sample of Consent Form.

Chapter 36 - Discourse studies mainly try to go beyond sentence boundaries and analyze natural language in use. The context where written, spoken or any kind of semiotic event take place is a major concern in discourse analysis. Corpus linguistics is also related to the real language in use by making analyses of large collections of written or spoken language samples. Apart from corpus linguistics' being more of a methodology rather than a discipline per se, the main difference between the two is that while structural and lexical patterns are in the foreground in corpus linguistics, discourse analysis embraces the idea that there is more than meets the eye in the real language in use. In this chapter, possibilities of integrating corpus methodology into discourse studies are sought.

Chapter 37 - Research on the effects of feedback on EFL writing is well documented, although Hyland and Hyland state: 'Given how few studies have been carried out, little is known about the relationship between teacher and student discourse and teacher feedback in conferences and student revision'. The qualitative action research study outlined in this chapter addresses this imbalance. It concerns teacher-conferencing on academic essays written in a higher education context in Turkey. Based on a model of interrelated practices for action research suggested by Burns, it investigates the relationship between discourse features of the conference and alterations made in follow-up drafts. Working with a constructivist approach to data, the study outlines how three Turkish teachers analysed transcripts of themselves conferencing in order to identify desirable features. Using such features, a second AR team repeated this procedure to investigate the relationship between the conference and amendments to follow-up drafts. The chapter outlines practical action research and conferencing. It looks in particular at the effect of two specific features of conferencing discourse: teacher-eliciting and the use of the L1.

Chapter 38 - Blogs have become a useful component in many language classrooms, with the benefits of contributing to incidental learning among students and promoting collaboration among all members of the classroom community and across the increasingly globalizing world. The usefulness of blogs in writing courses has been explored, but their role in increasing reading proficiency and critical thinking in reading courses is less clearly understood. This chapter aims to analyze the discourse of blog postings for evidence of critical reading and active engagement in college-level ESL reading classrooms. Fifty-six students in five advanced-level Reading classes in an English for Academic Purposes (EAP) program at a mid-size, public undergraduate college in the United States are described in this chapter. Over the course of each semester, the students posted blog entries about three novels on a weekly basis. In addition, the students completed a pre- and post-course survey measuring their attitudes towards reading and blogging. Discourse analysis of the blog postings revealed that students' critical thinking on the readings deepened over the course of each semester. The results suggest that blogging may be usefully implemented to improve students' extensive reading outside of class and active engagement with the text and other readers. Further, the feedback provided by the students in both the survey and in the blog postings themselves points to ways in which blogs can create a strong sense of community in ESL reading courses and similar environments.

Chapter 39 - Research into the general nature of the supervisory process in language education has recently gained popularity. This chapter includes the examination of the analysis of the mitigation discourse found in the supervisory interaction between two graduate students. To illustrate the submerging patterns of mitigation the author will examine the nature of the supervisory feedback sessions the author provided for two classmates, one of

whom teaching ESL and the other Chinese at undergraduate level, focusing on the effects of such devices observed in the transcripts of the two post-observation conferences held with the latter. Findings of this study discussed in this chapter recommend that mitigation be used as a strong pedagogical tool for the professional development of practicing and student teachers.

Chapter 40 - Learner errors and how course instructors should react to these errors have been studied extensively by many different people up to now. The aim of this chapter is to compare and contrast the basic corrective feedback patterns used by native and non-native speaker teachers of English in two different ELT settings, a Turkish and an American EFL setting. Classroom conversations of one native (NS) and one non-native speaker (NNS) teacher of English from Turkish EFL setting and one NS and one NNS teacher of English from American ESL setting in reading-based courses were video-recorded for four weeks and they were transcribed by the researchers. The findings of this chapter indicate that NS teachers of English are more tolerant about learners' spoken errors than NNS teachers of English but they try to correct as many pronunciation and lexical errors as possible. On the other hand, NNS teachers of English do supply corrective feedback for lots of grammatical errors but they are not as sensitive as NS teachers of English about the pronunciation and lexical errors in both contexts.

Chapter 41 - While numerous studies have been conducted into the effects of corrective feedback (CF), learners are not often asked their opinions on why they incorporate or reject such feedback in their revised work. The classroom-based study discussed in this chapter builds on a previous study in which feedback types and error types were compared to uptake rates on a revised audio recording. Since feedback and error types seemed to show very limited correlation with uptake, further investigations were conducted to explore students' reasons for their responses to CF. Twenty one students were shown the original comments and data about their uptake and then interviewed briefly to examine their attitudes and approaches to the assignment. Results reveal a variety of possible reasons why students may be more or less inclined to make changes to a second recording based on their teacher's CF. An heuristic device to help teachers prevent problems with similar assignments and increase uptake rates is proposed.

Chapter 42 - Corrective feedback has been the focus of debates for the past two decades. Researchers have been dealing with questions of its place in second language writing, its effectiveness, and if it helps (or harms) at all. The results of this previous research have led to the creation of terms for the classification of feedback, such as "direct/indirect," "focused/comprehensive," and "coded/uncoded." The study discussed in this chapter, which took place in an EFL environment in an English Language Teaching department, investigates the relative effectiveness of coded versus uncoded feedback by comparing two drafts of an assignment. The results indicate that the coded feedback is slightly more effective, but this may be due to discrepancies in the frequency with which each type of feedback was given. While no solid conclusions can be drawn, the chapter implicates that for revision purposes, both coded and uncoded feedback are far more effective for improving accuracy than leaving students to their own devices.

Chapter 43 - It has been estimated that some 60% of today's world population is multilingual. Living in a multilingual world makes language learning essential and the foreign language teaching profession even more valued to guarantee communication in a wide spectrum of languages, thus promoting mobility around the world and ensuring the continuity of the translation industry. The emergence of a dizzying array of digital technology tools

together with the advent of web-enhanced language learning and CALL are useful to assist during the language learning process, however, the use of technology as a mere replacement of more traditional ways of instruction does not work. The incorporation of the omnipresent Web.2.0 and its mobile, distance, blended and flipped learning opportunities can provide students with a wide variety of authentic resources for the development of both communicative and structural skills inviting them to collaborate and to develop language awareness and learning competences in the process. From the teaching perspective, it is imperative to take some time to reflect on the suitability of educational tools and the implementation of new pedagogies such as constructivism that support the integration of educational technologies in the curriculum without overlooking the importance of maintaining its social and cross-cultural dimension, with a view to encourage autonomy, and increase exposure to the target language and culture. This chapter presents illustrations of the latest trends and practices in language learning, demonstrating that technology-enhanced language learning enables innovative foreign language delivery and empowers learners to acquire the chosen language in a more independent yet effective way.

Chapter 44 - The chapter describes the results of an experiment in building an online platform for learning foreign languages that allows people to teach their native language without being professional instructors. This platform allows audio and video connections between the participants and includes an interface with pre-defined interactive lessons. The content is presented in the form of bilateral scenario cards. Each of the participants (the student and the teacher) follows their own version of the cards in the video chat. For each card presented to the student there is a corresponding card for the teacher containing step-by-step instructions for reading the text out loud or asking the student a question and showing the correct answer. The student can use prompts and translations if s/he does not understand the teacher. The teacher does not have to prepare for the lessons, because the system contains all the necessary teaching materials. This system allows separating the lesson material from the teacher. Thus, the teacher can be any native speaker. The main constituents of content development are: dual language prompts, repetition, comprehension and a dictionary. Four levels are implemented: preschool, beginner, intermediate, and advanced. Four languages are currently supported: English, Spanish, German, and Russian.

In addition to the system description, gamification and viral mechanics are also discussed. Relationships between virality (viral involvement of users) and retention parameters as measurable metrics are calculated and discussed using real examples. Virality and monetization can be both competing and complementary mechanisms for the system growth. The F-growth factor, which combines both virality and retention, is proposed as the metrics of the overall freemium system performance in terms of the user base growth. This approach can be tested using a small number of users to assess the system potential performance. If the F-growth factor is less than one, the product needs further development. If the F-growth factor is greater than one, the system retains existing and attracts new users, thus a large scale market launch can be successful.

Chapter 45 - In the EFL context, the learners' extracurricular contact with the L2 is considered both an important goal and a substantial means to develop and optimize their foreign language acquisition. From a cognitive-motivational perspective the extent and intensity to communicate in a foreign language outside the EFL classroom will not only depend on the learners' language skills, but will also be strongly affected by their related self-beliefs. In particular, their perceptions of their own competencies as well as their

apprehension concerning the use of the English language should decisively regulate their actual willingness to communicate in the L2. Besides pertinent listening, pronunciation, vocabulary or grammar skills, in particular, the learners' oral narrative competencies and their related self-beliefs, respectively, should claim a central role in determining their L2 contact. However, as previous EFL research could incrementally differentiate L2 competence beliefs and anxieties into several specific subcomponents (such as speaking, reading, or writing beliefs) and could clearly demonstrate the relationships of these subcomponents with the foreign language learners' relevant achievement and proficiency levels – the issue of oral narrative competence beliefs and anxieties appears to be barely analyzed. Moreover, little is known about their contribution to explain interindividually existing differences in EFL learners' extracurricular L2 contact. Therefore, the present study aims at clarifying these relationships. In a sample of $N = 256$ German ninth-graders from 9 inner-city grammar schools the relations between their related competence beliefs, anxiety, teacher ratings of their relevant L2 skills, and their extracurricular L2 contact were analyzed. For concurrent validation, measures of their L1 and L2 self-concept were also included. Using structural equation modeling method the results could show the learners' L2 contact being directly explained by their self-perceptions of oral narrative competencies, which appeared to be directly affected by their anxiety concerning oral narrative situations. The anxiety variable, in turn, could be directly predicted by the teacher rating of learners' speaking skills. Hence, the L2 speaking skills had no direct impact on the learners' L2 contact, but were sequentially mediated by their oral narrative self-beliefs and their apprehension or fear of failure concerning oral narrative situations. Furthermore, multiple group comparison could demonstrate these relationships among variables to be invariant across gender. Taken altogether, the present findings stress the need for conceptually and methodologically more complex research designs to intensely unravel the developmental pathways and educational effects of EFL learners' extracurricular L2 activities.

Chapter 46 - The present study examines how a learner who learns Japanese as a foreign language (FL) at an Australian university develops a positive FL self-concept to overcome her anxiety about speaking the FL during the transition period from secondary school to university and then to a Japanese study abroad. FL self-concepts are a newly developed research area in applied linguistics, in which individual differences of the FL learners have been increasingly focussed on as well as affective factors, such as learners' feelings associated with the FL learning and socio-contextual factors, such as their learning environments. FL self-concepts refer to learners' beliefs about themselves as FL learners including an evaluation of their competence in FL and feelings of self-worth related to the evaluation. FL self-concepts are closely associated with anxiety to speak the FL because learners' social or intellectual status may be threatened by making mistakes, which may provoke negative FL self-concepts. This anxiety may worsen during the transition to universities or the initial stages of study abroad due to the unfamiliarity of new learning environments. Developing positive FL self-concepts and overcoming anxiety is very important, especially in those periods of time, for learners to increase their skills in communicating in FLs. FL or second language (SL) self-concepts have been investigated in the areas of English as FL, Russian study abroad, and European languages, such as Spanish or Italian. However, no studies have been carried out in Asian language learning contexts. Therefore, the present study researches a learner's self-concept of Japanese as a FL.

Data were collected longitudinally for two years with diary writing, classroom observation and interviews (face-to-face and by Skype). A case study approach was used to closely examine how a learner's self-concept changes with detailed, personal and contextualised data. This learner was focussed on because she participated in the study both during transitioning to university and during study abroad and data collected from her were very detailed and informative. The learner hesitated to speak Japanese in the classroom at the beginning of the course due to the fear of making mistakes, which did not contribute to developing a positive FL self-concept. By preparing for the lessons more carefully according to her belief in the importance of practice, she became more confident and started speaking Japanese more often in class. Even after developing a positive FL self-concept in the classroom, she hesitated to speak Japanese outside of class in her study abroad. After developing her confidence in listening comprehension with frequent practice and having a critical experience, her FL self-concept in speaking became more positive. The present study found that the development of learners' FL self-concepts is not linear. Even after developing positive FL self-concepts in a particular learning environment, their self-concepts may become negative in a different learning context. The study also suggests that learners can develop positive FL self-concepts by making learning actions based on their beliefs about FL learning.

Chapter 47 - Teaching and learning is believed to be context bound, as what works in one context may be unsuitable in another context. Appropriate ELT methodologies are chosen in line with a variety of existing variables, including 'the constraints of the school or educational setting'. Unfortunately, innovations in approaches and methodologies have mostly been a reaction to learners' proficiency and the demand for specified competences by the public. This has prompted a series of ELT reforms from the sixteenth century England to the present. On the whole, reforms in the domain have been addressing vertical concerns as a result of the conservative understanding of the Englishness of ELT contexts. However, in recent times, English has spread beyond the borders of conservatism, thereby pushing the concerns of a homogeneous ELT landscape to more flexible and dynamic spectra of teaching and language use. In spite of this flexibility, the periphery still believes in the methodologies conceived at the Centre for the Centre. Due to the inapplicability of the methodologies in all contexts, a dividing line seems to exist between 'standard' contexts and 'under-resourced context'. This Chapter argues that the 'under-resourcefulness' of an ELT context is misguided, as it is derived from the conception of what is believed to be 'standard' and not on the concept of adequacy and sufficiency. Secondly, the Chapter hopes to demonstrate that the 'under-resourced' conception of contexts is the result of the inapplicability of Centre-driven methodologies in contexts that are only different and not actually under-resourced per se. The centrality of these under-resourced contexts in innovating ELT methodologies is posited.

Chapter 48 - Having considered the data of previous studies related to certain benefits of CLIL on students' linguistic and cognitive development, a project was piloted with 6th grade students (aged 11-12 years) of an experimental primary school in Northern Greece. The project, *From Michelangelo to Picasso*, aimed at introducing some aspects of cultural history in an alternative way and creating an educational environment that favors the art experimentation and expression in EFL (English as a Foreign Language). The project comprised 10 thematic axes that included all the important artistic movements from 15th to 21st century: "Renaissance", "Baroque, Rococo", "Neoclassicism, Romanticism", "Realism", "Impressionism", "Post-impressionism", "Expressionism, Fauvism", "Cubism, Abstract Art",

“Surrealism”, “Contemporary art (Abstract Expressionism, Pop Art, Performance, Installation, etc.)”. The project was carried out in three stages: a. The ‘Pre-task’ stage, where the students were introduced to the historic, artistic and ideological framework and the key-artists of each artistic movement. b. The ‘Task-Cycle’ stage, where the students were engaged into various group tasks involving experiential learning, problem solving and creative expression. In such an activity-based context students were exploring, communicating, and elaborating content knowledge in the target language. c. The ‘Language Focus’ stage was carried out in a game-based context. Activities such as role play games, pantomime, creative workshops, exhibitions, artistic presentations, quiz and puzzle games, debates, empathy were at the core of every thematic unit. In order to estimate the effectiveness of the project, *multi-method* approaches were employed such as, content-specific and FL pre/posttests, role playing, journals, portfolio and questionnaires. The data suggested that the CLIL module contributed to improving specific vocabulary and enhancing students’ communication skills. Concerning the subject matter, they expanded their knowledge on history of art approaching experientially and creatively the artistic, historical and ideological framework of the development of art in the western world.

Chapter 49 - Lexical inferencing strategies are important cognitive strategy not only for obtaining good level of reading comprehension but also an effective learning strategy in vocabulary acquisition. Closely related to lexical inferencing strategies is incidental vocabulary acquisition, the latter is seen as an essential prerequisite for the latter, and the latter is viewed as one of the products of lexical inferencing strategies. This chapter systematically and critically reviews a variety of factors which influence lexical inferencing strategy use and incidental vocabulary acquisition among foreign language (FL) learners. The chapter concludes with some directions for researchers to consider in the future research.

Chapter 50 - The New Literacy Studies encompass a notion of language as a social practice and the understanding that it is necessary to foster the development of critical thinking in citizens/students, aiming at citizenship education and social change. This chapter aims to introduce the theories of New Literacies and Critical Literacy and their relevance to research in the field of Teaching English as a Foreign Language (TEFL) and Teacher Education. The chapter presents and discusses a group of recent theories that serve as the theoretical basis for a possible epistemological change in Teaching English as a Foreign Language, especially in public schools. The chapter starts by presenting Literacy Studies and how the concept of Literacy has changed lately and goes on to discuss the New Literacies Studies and Multiliteracies. The well-known autonomous and ideological models of literacy are also presented and discussed in the chapter. Throughout the chapter, some examples to the fields of English as a Foreign Language (EFL) and Language Teacher Education are also presented and implications to research and practice in these areas are discussed. The chapter takes the perspective of EFL teaching in Brazil, where the research was conducted.

Chapter 51 - This chapter provides an update on a decade of neuroimaging studies (using electroencephalography, EEG, and magnetoencephalography, MEG) that have focused on linguistic processing in patients with aphasia. The goal of this chapter is to shed light on the challenges and usefulness in using such techniques for the study of aphasia. The authors review study objectives, techniques and results, and highlight the linguistic structures that have been studied. The first part defines the challenges and usefulness of EEG and MEG techniques for aphasiology; the second reports the procedures, targets and main results of

reviewed studies; the last section addresses the following issues: What does neuroimaging add to classical behavioral studies on aphasia? Are they both necessary and why?

Chapter 52 - Recent advances in neuroimaging have allowed for insight into the millisecond-by-millisecond unfolding of language processing in the brain. In particular, event-related brain potentials (ERPs), non-invasive measures of scalp-based EEG (electroencephalographic) recordings of underlying brain activity, can reflect on-line neurocognitive processes involved in linguistic processing. In this chapter the authors will present a review of ERP research focusing on lexical-semantic, morphosyntactic and syntactic processing during language comprehension in children with and without specific language impairment (SLI). The authors will highlight results important for our understanding of SLI, as well as methodological issues and challenges involved in ERP research.

Chapter 53 - Concerned about traditional practice with respect to challenging behaviors of learners with learning difficulties and disabilities (LLDD) in the UK, the author questioned the extent to which they could manage themselves. From 265 LLDD, the author invited 15 male learners, median age of 19, to participate in 12 weekly 1 hour discussions in sense-making groups specific to the challenging behavior of 3 case study LLDD who were drawn from the 15, as well as in 12 weekly 1 hour interviews that addressed behaviors recorded by practitioners (someone who works within a particular paradigm of care and education) as challenging. Thematic analysis yielded 5 themes related to different versions of LLDD either acting responsibly (handing their problems over to practitioners) or irresponsibly (deliberately disrupting learning and social environments), categorized as *I've got a problem, I told staff, I can't, I'm disabled* and *I'm not normal*. Discursive analysis highlighted 5 variable communicative and behavior patterns, *Conditioned-Response, Role Specific, Inner-Conflicted, Retreating* and *Higher Order*, which correlated with LLDD levels of differentiation from various adverse sources of influence on their identities. Despite these influences, when invited to engage non-defensively, LLDD proved able to manage themselves.

Chapter 54 - Mental speed is defined as the speed at which neural processes are completed and it has been found that individual performance on speed measures significantly correlates with fluid intelligence scores. Given that tradition measures of mental speed use a discrimination judgment, the goal of this research was to expand upon the design of inspection time tasks, in which the exposure time for sensory stimuli is manipulated. In this study, mental speed was assessed using several novel inspection time measures that involved speeded letter detection and identification, along with letter-pair comparisons. The letter detection time task was considered to be the most basic measure of time needed to accurately perceive the presence of the stimulus, whereas letter identification requires the addition of verbal processes to label the stimulus. For each measure the time for the presentation duration of the target stimuli was varied from 80 to 16 milliseconds. In addition to the 3 inspection time tests, both fluid intelligence and working memory capacity were assessed. Fluid intelligence was assessed using a standardized visual reasoning test (Ravens), while working memory capacity was observed using a computerized complex span measure (Counting Span). Performance data for the inspection time tasks indicate that detection task was significantly easier, even under extreme time constraints for stimulus processing (16ms) in comparison to the letter identification and discrimination versions, in which accuracy dropped more drastically with decreasing inspection time. Correlational data revealed that all 3 speed measures predicted intelligence, however, only identification was related to working memory.

Both mental speed and working memory capacity are significantly correlated with fluid intelligence, but each process makes a unique contribution to intelligence.

Chapter 55 - Compounding is an effective way to express new meanings by combining existing concepts. However, the resultant meaning involves not only the sum of meanings of the two constituent concepts but also the semantic relation between them. Compounding is particularly important for the study of Chinese word recognition as compound word is the dominant type of vocabulary in Chinese. The present commentary describes two recent studies using event-related potentials (ERPs) to examine the time course of lexical processing for Chinese compound words. In the first study, the authors reported the discovery of a novel ERP component, named the centro-parietal N200, which was elicited about 200ms after the onset of two-character words. Evidence suggests that this N200 reflects recognition of the two characters' orthographic form. In the second study, the authors used a relation priming paradigm and showed that the relation combining meanings of the two characters was activated in the N400 time window about 80ms later than the meaning activation of the individual characters. Together, the results indicate a clear serial process in reading compound Chinese words, first recognizing the word form around 200ms following word presentation, and then starting to retrieve each character's meaning at around 260ms, and finally integrating the two constituting meanings at around 340ms.

Chapter 56 - In language teaching and learning, major roles belong to teachers and learners. Active involvement of these two parties necessitates profound background knowledge of factors which affects the process of learning and teaching language. Deriving from this knowledge, the teacher develops his skill in teaching; the learner learns how to become more successful in achieving his goal, i.e., to learn another language. This chapter will present the basic factors about learners and the basic characteristics of teachers.

Chapter 57 - Planning is a necessary step no matter what business you are involved in if you want to achieve your goals. If we consider teachers as "the managers" of the student learning, s/he also needs to know exactly what s/he intends to do in the class. There are four main things that a teacher needs to know before going to the class to teach: the aim of the lesson; what new language the lesson contains; the main stages of the lesson (when and how to organize different activities); what to do at each stage.

A lesson plan is a very useful tool which can be seen as a combination of guide, resource, and historical document reflecting our teaching philosophy, student population, textbooks and most importantly, our goals for our students. Jensen also suggests that "a lesson plan is essential for novice teachers and convenient for experienced teachers".

Chapter 58 - Most of the undergraduate and graduate level English Language Teaching programs offer courses in Linguistics, Language Acquisition, Approaches and Methods, Methodology and Teaching Language Skills as well as Practicum and School Practice. All of these courses provide the necessary skills and knowledge to help student teachers become skillful and adept practitioners. Usually, Practicum and School Practice courses are offered late in the program. Until the Practicum and School Experience courses, many of the foundational courses in ELT programs do not focus on the practical aspect of teacher preparation. Microteaching, as a technique for teacher education, can address some of these problems and help the student learn the process of becoming practitioners while they are taking some basic foundational courses. It is also commonly used as a component of in-service teacher development programs for various types and stages of professional development. This training procedure focuses on the simplification of the complexities of the

regular teaching-learning process by minimizing any of these aspects: class-size, time, task and content. It also adds the immediate and delayed feedback opportunity from various resources.

Chapter 59 - What language skill comes into your mind first when you are asked to define the term fluency in a foreign language? "...people who know a language are referred to as 'speakers' of that language, as if speaking included all other kinds of knowing". Speaking seems to be intuitively regarded as the most important skill of all the four language skills. In fact, many language learners consider speaking as equal to the overall language competence, and they measure their language proficiency, their accomplishments and their progress through learning based on their speaking skills. Fluency is then strongly associated with and measured by the ability to converse with others, much more than the ability to read, comprehend oral language or express oneself on a written document. In many contexts, people judge a language user 'at face value' upon speaking skill. In other words, people form judgments about our language competence from our speaking skills rather than any other skill.

Speaking can be defined as "the process of building and sharing meaning through the use of verbal and non-verbal symbols, in a variety of contexts". Speaking plays a crucial role in foreign language learning and teaching. With the internalization of English as the medium of communication, the need for meaningful and successful interactions has become more imperative than ever. Students should not only form grammatically correct sentences, but also use these sentences in appropriate social contexts taking into account the cultural background and social status of the interlocutor (the person(s) they are talking to).

Chapter 60 - Listening is one of the basic skills because it is essential for communication. For Doff, if we want to improve speaking skills, or conversational skills, we need to develop listening skills; students need to understand what they hear. This can be achieved through listening to enough English at normal speed. Unless we are teaching English at a country where it is spoken, we need to give students plenty of opportunities to listen to English in the classroom.

Some people believe that listening is neglected in language teaching since it is seen as a normal reflex. "In reality, listening is used far more than any other single language skill in normal daily life. On average, we can expect to listen twice as much as we speak, four times more than we read, and five times more than we write. There are other studies which show the importance of listening. One of them was conducted by Wilt and it goes back to 1950s.

In this study it was found that 45% of communication was listening, 30% speaking, 16% reading and 9% writing. In another older one, Rankin found that 70% of waking time was spent communicating. In short, all these studies highlight the importance of listening and communication in English language learning. It is believed that when learners listen to authentic English video and audio materials for a long time, they can produce better sentences more quickly than learners who do not do so. This is very important for learners who are learning English in non-English-speaking countries. To illustrate, when students listen to dialogues, discussions, debates, interviews, etc., they can practice the content of various topics and vocabulary by hearing the way people speak in real life. Another useful practice can be discussing issues after listening to texts or programs in English.

To sum up, through listening, learners can modify the things they hear, and by imitating, they can learn certain structures, vocabulary items, pronunciation, and speaking skills can

develop. Psychologically they will feel better and more comfortable when listening than when speaking, because they do not produce anything but just receive input.

Chapter 61 - This chapter examines the segmental and supra-segmental problems in a short excerpt from video recordings of accented speech and argues that it does not necessarily cause intelligibility problems and can be used as a model for ESL learners with the same L1. The informants used in this study are, Galip Abacı and Aylin Dolu, pseudonyms for two senior students at the English Language Teaching Program at Kocaeli University, Faculty of Education. The two informants were videotaped during thirty minute interviews at the faculty of Education while answering questions about their opinions about Turkey's foreign policy. My reason for studying accented but intelligible speech samples is that the author find it interesting not only because it is a reality but also a very viable option for the majority of EFL/ESL speakers worldwide who are not likely to attain native-like L2 speech no matter how hard they try. As Murphy suggests "accented speakers may serve as more realistic models of L2 pronunciation achievement and, in many cases, of societal accomplishment as well." Furthermore, "the speaking proficiency of an AIC (accented, intelligible, and comprehensible) speaker of English represents a sufficient and attainable level to which pronunciation teachers can feel confident in encouraging learners to aspire". The idea of intelligibility has become central to the teaching of pronunciation... the idea was slow to feed through to practice, but in the 1970s many English teachers worldwide came to realize that it was unrealistic, time-consuming and potentially inhibitory to aim for a native like accent (Field, 2005:400). This led to the abandonment of traditional checklist approaches to pronunciation instruction and intelligibility was adopted as a criterion. As a Turkish L1 speaker myself, the author think that there is great potential in focusing on speakers like the two senior ELT majors at a Turkish university in that they are very likely to be perceived as intelligible hence successful EFL speakers by a possible target audience of this work, my first year undergraduate students at the EFL Education program of Kocaeli University in Turkey.

Chapter 62 - The shift from form-focused foreign language instruction paradigm to a lexically oriented one has been voiced for more than a couple of decades. Although lexical competence was already defined as one of the most crucial indicators of general language ability decades ago, some other researchers, after a couple of decades, stated that L2 lexicon is in a rediscovery period. This means that the importance of lexicon in a foreign language has always been accepted but has only been gaining attention recently. As is always the case, when a topic is considered to be worth learning, the well-known questions what to teach about the topic and how to teach it arise.

Chapter 63 - One day an English teacher goes into the English class, and hears some students talking about writing in English. "Do you like writing?" asks one of them to the others silently. Most reply anxiously and simultaneously "Nooo!!" The answer is unfortunately but not surprisingly a big "No" and the teacher feels a bit desperate. "It is difficult," one says. The other adds "I simply can't write." "It takes time," another says. One murmurs "It's boring. I hope this new teacher knows what to do." Hopefully, the new teacher knows how to overcome these problems in an EFL/ESL class.

What makes writing in English somewhat difficult for learners is a matter question for teachers of English for ages. Writing is productive skill and requires thinking many aspects of language such as sentence structure, grammar, spelling, vocabulary, punctuation, layout besides the content, organization, feedback and the grade they will get. Furthermore, if time is limited while writing, then the murmurs start in the EFL/ESL class. How did you feel as

learners when you were assigned to hand in a written work in your English class as a young learner?

On the other hand, do teachers like teaching writing? Most teachers will probably answer this question hesitantly as they think about the workload after students have written any kind of text, then start asking “Why should we teach writing? What writing activities should we do in class? Will we correct every mistake? How will we correct and assess them? How will we give feedback to each student?” The answers of all these questions have to be clear for both English teachers and EFL/ESL students. Therefore, when the right decisions are given, the right steps are followed in teaching writing to students in an EFL/ESL class, students become more motivated and encouraged to write in English and teachers are more willing to do writing tasks.

Chapter 64 - Language is an important means of communication. People learn how to convey and share the meanings of things through language. The relationship between second/foreign language acquisition and communication can be best explained by Halliday’s language-based theory of learning principal. According to Halliday all learning is a linguistic process and consists of three interwoven language functions: learning language, learning content through language, and learning about language.

As a complicated system language includes “small elements that can be combined in an infinite number of ways in order to make larger structures”. The four dynamics of language are phonology, morphology, syntax, and semantics. The phonology is the sound system of a language and a set of rules that control how they can be combined. In other words, it is the audible quality of language. Morphology is the forms of words, and the ways these forms of words are related to other words. Syntax is the rules for the formation of sentences and phrases in which words can be combined. Finally, the semantics is the study of meaning in language. It includes the meanings that emerge from all of the previous three elements: the sounds, word meanings, and word-order patterns. Phonology, morphology, syntax, and semantics exist in all languages. However, a writing system, or orthography may not exist in every language. The other four universals of language (phonology, morphology, syntax and semantics) are naturally acquired by native speakers of a language. On the other hand, orthography is not naturally acquired and needs to be taught since it is related to literacy. Pinker supports this claim by stating that, “Language is an instinct, but reading is not”.

In language learning there are four skills that learners need for complete communication: listening, speaking, reading, and writing. In the first or native language, people have all these skills and background knowledge that is needed to communicate. So, they are probably not aware of the complexity of the process. However, in second/foreign language acquisition the four skills represent a particular pattern. Though they are stated in the same order with first language, generally listening and reading are characterized as “receptive,” and speaking and writing as “productive”. However, we should be cautious in drawing precise lines between them “because they fail to capture the active meaning making that takes place during both listening and reading”. The four skills need to be included in the Foreign Language (FL)/ Second Language (SL) curricula both for instructional planning and assessment. Thus, this chapter particularly focuses on reading skill in foreign language learning.

Chapter 65 - In the language classroom, one of the most important parts of being a teacher is presenting new language, supplying some opportunities to practice it and make revisions when necessary. Whether to teach grammar or not has always been a controversial issue among researchers and practitioners of language teaching. Even though it is

acknowledged that people learn languages differently, the process of learning becomes easier if they are able to perceive regularities and patterns. However, we are all familiar with students who are really good at identifying grammatical structures and who can list the basic usage related to each of them but who cannot use them in real communication. As suggested by Larsen-Freeman (2001), grammatical knowledge is important as long as it enables learners to communicate “correctly, meaningfully and appropriately”. In order to emphasize the inadequacy of form-based teaching and going beyond form, she suggested her three-dimensional framework including “form”, “meaning” and “use”. Larsen-Freeman (2001) pointed out that if students are not aware of the fact that grammatical structure has these 3 dimensions, they are prone to making mistakes even if they know the rules of the target language. In order to explain the connection between these dimensions, Savage et al. (2010) give the following example:

Form: MUST + the base form of the verb (infinitive without to)

Meaning: obligation or necessity

Use: formal, used much more in writing than in speaking. In speaking, people tend to use “have to”.

According to Freeman’s this three-dimensional framework, when students are aware of all these three dimensions of modal verb “MUST” in English, they will be able to use it correctly, meaningfully and in appropriate situations.

Chapter 66 - Realistically, how often do you talk without listening? Or write without reading? For just about most situations we can imagine from our daily lives, several language skills are used simultaneously for communicative purposes. In the past several decades, much evidence has emerged that, in order for learners to attain competence in a language, teaching needs to integrate both linguistic and communicative skills.

Chapter 67 - Using literature to teach language skills has been a matter of discussion since the 1960s. However, the use of literary works to teach languages dates back to a much earlier period. During the 19th century the primary means of language teaching was the grammar translation method. The practitioners of this method would view and exploit literary texts as rich sources of translation. During this period works of literature were regarded as efficient pedagogical materials. Through the translation of literary texts in their mother tongue, the students were made to practise such language skills as grammar and vocabulary. However, the onset of direct and audio-lingual methods during 1960s and 1970s brought about a radical change of opinion as to the use of literature as a language teaching tool. These methods that seemed to rise upon structural approaches put heavy emphasis on form thereby dismissing the role of literature in teaching a foreign language. From this point onwards purely linguistic concerns overshadowed the use of literary works for language teaching purposes. Even the emergence of CLT in the late 1970s and early 1980s could not prevent the exclusion of literature from the language teaching curricula. According to Maley, one of the main reasons of this trend against the utilization of literature as a pedagogical tool was the lack of empirical research that would manifest the potential of literature as a beneficial language teaching source. Following a long period of silence, the use of literature in the language classroom experienced a revival starting from the middle of the 1980s. Under the influence of communicative trend, literature started to be regarded as a tool to assist the development of mainly communicative competence as well as “a springboard for the development of critical thinking and aesthetic appreciation” which also contributes to the students’ awareness on the culture and society of the relevant country. Recognizing their

potential, many linguists began to view literary works in the classroom as authentic, pleasurable and cultural material. Since this reemergence of literature in the realm of language teaching, not only the use of literary works but also research, both empirical and theoretical, as to their role in language teaching has gradually gained momentum. Today, particularly the popularity of interdisciplinary studies has brought about an even greater focus on the pedagogical potential of literature particularly for language teaching purposes. Despite the difficulties of incorporating literary works in ELT curriculum, works of many scholars in the field strongly argue for the benefits that inclusion of literature would potentially bring. Many studies conducted by Lazar, Cook, and Shanahan draw attention to the potential that literature holds as a language teaching tool.

Despite the concerns stated by a few linguists and educators, there has been a great deal of research that speaks in favor of literature as a pedagogical tool. Bradford introduces three ways through which works of literature are likely to be conducive to success in language teaching. First of all, literature provides a rich source of vocabulary for the language learner. The second contribution of literature according to Bradford is the exceptional sentence structures that it hosts. Getting familiar with these structures in authentic settings is an advantage for language learners. Povey holds a similar view asserting that with its rich vocabulary pool and complex syntactical patterns literature helps language learners develop the extent of their proficiency levels both in terms of language use and linguistic competence. Finally, literary works introduce new cultural perspectives and give the chance to have a language experience in real life settings. As McKay states literature can be used to enhance awareness of students as to the diverse uses of language. Another important contribution of literature to language learning is regarded as its effect on critical thinking skills of students. Oster suggests that literature provides students different perspectives, which in turn extends students' vision and encourages critical thinking. Lazar draws attention to a similar potential by pointing out that literature might become a language teaching tool by fostering discussion, controversy and critical thinking. Another important benefit of literature is that through exposure to language intended for native speakers, students have the chance to learn different forms and conventions. In this respect, literary works become real and meaningful models for language learners. One of the most detailed accounts trying to justify the role of literature in language teaching comes from Maley, who lays out a number of reasons to use literary works in EFL/ESL settings: 1. Universality: All cultures and languages follow a certain literary tradition, which involve common themes such as nature, death, love and separation. 2. Non-triviality: Literary texts present real and meaningful materials unlike the artificial trivialized language teaching resources. 3. Personal relevance: the events, views and emotions embedded in literature are relevant to learners' own experiences, so they can find or imagine correlations to their personal lives in works of literature. 4. Variety: Literary texts appear in a multitude of different forms and contents. This makes them enjoyable and motivating for language learners. 5. Interest: Literature deals with familiar subjects in an interesting and appealing manner. 6. Economy and suggestive power: Through literary devices, literature has the power to say much with a minimum amount of expression. 7. Ambiguity: The perceived meaning in literary texts can vary from individual to individual, which makes it an invaluable source for discussion and interaction.

In today's text books students have little opportunity to be involved in authentic use of language. The settings and activities provided by these materials are mostly artificial and remote from real communication. Literature requires students to actively participate in

meaningful activities and eliminates the disadvantages of mechanical process which is unfortunately still predominant in EFL/ESL classrooms worldwide. Duff and Maley bases the need for the incorporation of literature into language teaching curriculum upon its “linguistic, methodological and motivational” potential. Unlike the referential features of traditional text books and materials, literary texts are representational, which helps learners to use and develop their cognitive skills.

Chapter 68 - Although Task-Based language learning (TBLL), also known as task-based language teaching (TBLT) or task-based instruction (TBI), is quiet a popular term in ELT field, this methodology do not seem to have a fixed definition. However, it can be defined in general terms as Foster suggests:

TBLL methodologies share a common idea: giving learners tasks to transact, rather than items to learn, provides an environment which best promotes the natural language learning process.

This method has become a corner-stone of many educational institutions and ministries of education around the world. This might result from the fact that it gives an emphasis on “means” rather than “product”. It has gained popularity as it also encourages learners to be reflective learners, and welcomes a wide range of learning styles. Learning with an explicit sense of purpose is key to student motivation and involvement and, thus it is consistent with current theories of education. Another reason for TBLL to be a keystone approach might be the fact that learning occurs most effectively when related to the real-life activities performed by the learner. Focusing on the use of authentic language and asking learners to do meaningful tasks such as visiting a doctor, calling customer service for help or conducting an interview, while using L2, this method enables students to investigate the language in a non-threatening environment and teachers to achieve initiating reflective learning and teaching.

Chapter 69 - Cognitive linguistics emerged as a movement in the mid-1980s. Although in some sense it represents a new direction for linguistics, cognitive linguistics also builds upon venerable traditions, re-connecting the discipline with its past rather than severing ties and striking off in a revolutionary direction. Originally inspired by work by psychologists on the structure of human categorization in the 1970s, cognitive linguistics has maintained its commitment to psychological and neurological plausibility. Cognitive linguistics views linguistic cognition as indistinguishable from general cognition and thus seeks explanation of linguistic phenomena in terms of general cognitive strategies, such as metaphor, metonymy, and blending. Grammar and lexicon are viewed as parts of a single continuum and thus expected to be subject to the same cognitive strategies. Significant developments within cognitive linguistics in the past two decades include construction grammar and the application of quantitative methods to analyses.

Chapter 70 - Cognitive grammar belongs to the broader traditions of cognitive linguistics and functional linguistics. It emphasizes the symbolic function of language and the crucial role of conceptualization in social interaction. It is based on a conceptualist semantics recognizing the central importance of construal, i.e., our ability to conceive and portray the same situation in alternate ways.

A properly formulated conceptualist semantics makes possible a symbolic account of grammar. It is claimed that lexicon and grammar form a continuum fully describable as assemblies of symbolic structures (form-meaning pairings). Grammar is therefore meaningful, and valid grammatical notions have conceptual import. By way of example, a variety of evidence is cited to support semantic characterizations of subject and object.

Chapter 71 - This chapter provides a comprehensive and critical review of the major theories and models of conceptual combination, by highlighting agreements and controversies in the literature, and identifying future directions for research. The review summarizes the basic arguments of ten major models and then presents an analytical framework to compare and contrast these models along four dimensions: (1) the causal role of schemata in the model, (2) the role of cognitive harmony or consistency in the model, (3) the pragmatic orientation in the model, and (4) the explanatory scope of the model. The review identifies areas of agreement and disagreement among the various models and theories and calls for a synthesis theory to address various theoretical weaknesses and empirical gaps in the current explanations.

Chapter 72 - In part based on Nie and Chen, this chapter studies the complicated semantic networks of WATER. It demonstrates that the concept of WATER has found its way into all major components of the Chinese language: its writing system, its morphology, its semantics, and its syntax. The result is a multidimensional network of networks. The forming of these networks—and the eventual super-network—is due not only to conceptual metaphors/metonymies but also to other factors such as perceptual considerations and social values. In addition, since meaning is found to exist at the level below the written word, in the radical, the paper raises some important issues regarding the linguistic status of radicals in the language.

Chapter 73 - The progressive construction has a tripartite symbolic structure in which the auxiliary verb symbolically links up with the meaning component of TENSE, the main verb with the expressed SITUATION, and the present participial realization of the main verb with the aspectual category of IMPERFECTIVITY. The present paper focuses on each of these symbolic links and their interplay, and investigates the meaning construction processes involved in the symbolic structure of the progressive construction. Drawing on Croft and Wood's [2000] model of construal operations—revised in Croft and Cruse [2004: 40–73]—the present paper provides an overview of construal operations that are likely to be at play in the construction of the aspectual and actional meaning components of the progressive construction. The discussion also involves instances of the progressive construction, which display low semantic compatibility, as the ensuing semantic coercion involves a number of construal operations that are revelatory to the meaning construction of the progressive in general.

Chapter 74 - This chapter explores two fundamental tenets of Cognitive Grammar (CG) with reference to the meaning of the English pronoun *it*. One tenet is that all linguistic elements posited in language have conceptual (semantic) import. On the basis of this tenet, the author argues that the pronoun *it* is meaningful and its multiple senses can be characterised in terms of a prototype: a central sense from which other senses are somehow derived. The other tenet is that the meaning of a construction, as reflected in its particular morphosyntactic organisation, evokes a particular construal (imagery) imposed on its content. On the basis of this tenet, the author argues that a construction containing the pronoun *it* is motivated by the construal of scope: the array of conceptual content, narrow or broad, which the speaker chooses to characterize an expression. In a narrow scope which is represented by a non-extraposed construction, the speaker considers a minimal range of content in describing the situation. In a broad scope which is represented by an extraposed construction, the speaker considers a maximal range of content in describing the situation. The speaker's ability to construe a situation in a variety of ways is considered a key concept in CG.

Chapter 75 - The present chapter analyses Portuguese concessive constructions introduced by *apesar de* ('in weight of') and *embora* (from Old Portuguese *em boa hora*, 'in good time'). From the standpoint of Cognitive Grammar, it is argued that the constructions display a prime example of iconicity. Thus, it is shown that iconic principles such as linear ordering, formal complexity and formal distance explain the reason why the *apesar de* construction prototypically designates a more direct concessive relation, while the *embora* construction designates a more complex relation to the main clause. Further, it is claimed that the complex relation between the *embora* construction and the main clause represents a prime example of subjectification. Finally, the analysis shows that the subjunctive mood in the *embora* construction is related to the notion of dominion.

Chapter 76 - This chapter, firmly anchored in the framework of Leonard Talmy's cognitive semantics, reconstructs a core semantics of the English verb *seem*, which is considered a central instantiation of the schematic system of cognitive state. This 'new' semantics is meant to overcome the indecisiveness of recent accounts how to categorize *seem* (and its equivalents in other European languages): either as evidential or as epistemic or as both, and concomitantly identifying the meaning of *seem* with the meaning of the various constructions of which it is a constituent. To this end, the semantics of *seem* is here associated with Talmy's concept of the comparison frame, which places alternative conceptualizations of a situation within a single frame. In the case of *seem*, these alternatives are either 'fictive' or 'factive', juxtaposed in an ambiguous figure-ground configuration, which may be disambiguated by what in Talmy's ongoing research on the attention system in language is called non-dedicated lexical triggers (like *really*, *just*, *merely*, *only*). Conceived of as an incentive for further investigations of how schematic systems are 'recruited' to integrate, the paper at the same time testifies to the explanatory power of Talmy's Overlapping Systems Model of Cognitive Organization.

Chapter 77 - Within Talmy's and Slobin's typological framework, German belongs to satellite-framed languages, which generally express the path of motion in satellites and the manner of motion in the main verb. For Talmy, the expression of the path is the most basic information, it constitutes the core component; the manner expression is a subsidiary dimension. Many studies have focussed on the typological differences between different languages based on the path expression and have paid less attention to the expression of the manner dimension. Our study aims at taking a closer look at this neglected dimension of the manner of motion as it is realized in German. It will show that German is characterized by a manner salience which is realized at different levels of lexicalization and which is not restricted to motion and location verbs as the core of the lexicalization pattern. The manner of motion is typically also expressed in complex prepositional groups, especially with the preposition *bis* ('up to/till/until'), or at the level of complex local adverbs or postpositions which are hardly translatable into other languages. Constructions with complex particle verbs which combine a particle expressing a path of motion with a simplex verb that expresses a manner (but not a motion), constructions with a non-motion manner verb accompanied by a path satellite, or syntactic structures that combine a modal verb with a path satellite are typical for the German language as they combine in one structure expressions of path and manner of motion. The study presents the theoretical aspects of these different categories highlighting the «German way of thinking and speaking». It further illustrates the difficulties encountered when trying to translate the above examples into the verb-framed language French, which often omits the expression of manner.

Chapter 78 - For both literal and metaphorical motion, languages like English tend to express path in the satellite following the main verb of the sentence, freeing the verb to convey manner of motion information. In contrast, languages like Spanish tend to express path of motion in the main verb and less often directly convey manner of motion. Interestingly, theories about metaphor processing differ in the emphasis they give to cross-linguistic differences. In two studies, the current investigation examined 60 (30 English-speaking, 30 Spanish-speaking) adult participants' judgments about and reaction times for literal and metaphorical motion in familiar phrases (Experiment 1) as well as novel motion event metaphors (Experiment 2). Results suggest that English speakers both more frequently identified familiar metaphorical sentences when they included a manner verb and were faster at making these judgments than were Spanish speakers. With novel metaphors, English speakers picked the literal match at a proportionally greater rate than did Spanish speakers and did so more slowly than did Spanish speakers when sentences contained a path verb. These results indicate that English and Spanish speakers approach the task of interpreting metaphors in different ways depending on the type of verb that is used in the sentence.

Chapter 79 - This chapter compares and contrasts the metaphoric/metonymic conceptualisations of ANGER in English and Akan, a West African, Kwa, language within the general framework of conceptual metaphor theory (CMT). Studies on cross-cultural conceptual metaphors/metonymies in the cognitive linguistic tradition, particularly, those that concern emotion concepts, reveal both similarities and variation. The cultural embodied prototype theory explains this phenomenon by positing the cultural embodiment hypothesis. The paper particularly focuses on the language-specific construals or elaborations of shared conceptual metaphors of ANGER in the two languages to argue in support of the cultural embodiment hypothesis, namely that embodied cognition (as is reflected in the metaphorical/metonymic conceptualisations of emotions) is based on both universal human experience and culture-specific experience. The linguistic evidence in this chapter suggests that universal human embodied cognition works only at the generic/highly schematic level of conceptualisation. However, they are given language-specific elaborations or construals that are grounded in cultural salience (cultural embodiment). Using both primary and secondary data, this chapter contributes to the universality versus language-specificity of emotion conceptualisation debate by bringing evidence from a less known language/culture.

Chapter 80 - This chapter's focus are verbal sequences which, in the written modality of alphabetical orthographic systems, are marked off from their linguistic environment by a conventionalized set of figural elements out of a non-alphanumeric representational system (typically, parentheses, dashes, or commas). As these parenthetical constructions are (even traditionally) associated with some notion of attention, Talmy's (forthcoming) factor model of linguistic attention, informed by a sophisticated theory of language-specific attentional parameters, offers a coherent theoretical and powerful analytical framework that is both sufficiently independent and general to allow for a systematic and encompassive investigation of these constructions' attentional specifics. Proceeding from Talmy's analysis of parenthetical delivery in the spoken modality, some initial suggestions will be submitted of how to adapt his insights into attention and parentheticality to the particular conditions and specific demands of the written language: Two fundamental attentional mechanisms from a category of causal factors affecting linguistic entities in the context, Backgrounding the target and Targeting a concomitant of a referent, are scrutinized for a systematic analysis of major constructional variants of parenthetical constructions. Applying this novel and promising

approach, it proves sensible to delineate an attentional profile of (the) parenthetical construction(s) based on a(nother) pivotal factor, The generalized form-semantics association.

Chapter 81 - The social and embodied nature of language has recently been making strides into the understanding of language use and development. This chapter attempts to build upon and further integrate these perspectives by looking at metonymy from a sociocognitive as well as dynamic perspective. Firstly, Geeraerts' diachronic analysis of prototypicality and Peirsman and Geeraerts' prototypical patterns of metonymy are outlined in the context of the Peirsman and Geeraerts and Croft exchange regarding whether metonymy's part-for-whole relation is one of association or contiguity. Secondly, using metonymy as the principle example, this chapter proposes that communication is socially embedded through intersubjectivity and joint attention. Thirdly, it suggests the part-for-whole function of metonymy may also be similar to the whole-within-whole principle found in a *holon*. Fourthly, it proposes that this function is related to the dynamic complex systems principle of self-organization and that it acts to embody brain-body-environment triads. As such, the addition of more socially embedded and dynamically embodied grounding to metonymy's typical cognitive analysis in turn also suggests a similar triadic representation (i.e., dynamic socio-cognitive). Additionally suggested is that the understanding of prototypicality can benefit from being rendered as part of the dynamic process of the continuity of the mind, or as an *attractor landscape*. This chapter concludes with the proposal that the socially embedded and dynamically embodied nature of metonymy's part-for-whole or whole-within-whole prototypicality is an instantiation of the ability to off-load cognition onto the environment.

Chapter 82 - The main question addressed is whether emotional prosody of interjections, which show a non-arbitrary – indexical – relation between expression and meaning, could be integrated in the lexical representation, and whether this differs between high-lexical interjections and low-lexical interjections. Swedish high-lexical interjections have a more defined semantic content and can be understood without prosody, for example, hurrah, while low-lexical interjections are more ambiguous and can't be understood without the appropriate prosody, for example, oh. Lexical decision experiments were performed with high-lexical and low-lexical interjections having matching or mismatching prosody. The main hypothesis is that mismatch will slow down reaction times, especially for the low-lexical interjections.

The results of the experiments show that (a) stimuli with mismatch between lexical content and emotional prosody were recognized more slowly than matching stimuli, (b) low-lexical interjections were recognized more slowly than high-lexical interjections in mismatching conditions. The stimuli words were analysed acoustically with regard to F0 variation and duration, to pinpoint whether differing reaction times are dependent on acoustic variables or whether they depend on the mismatch condition as such. The comparison between the reaction times and the acoustic analysis shows that (c) reaction times are partly dependent on the specific emotion: different emotions have different durations and reaction times. However, the durations were not correlated with reaction times in matching and mismatching conditions.

The conclusion is that it is the mismatching prosody as such which affects reaction times, and that low-lexical interjections are affected more by mismatch than high-lexical interjections. It is further claimed that low lexical interjections with different emotional prosodies are in fact not homonymous, or polysemous, but that they can be seen as different morphemes since they have different meanings and different forms. Interjections have a

certain degree of emotional-prosodic specification in the lexical representation and emotional prosody is part of the phonological representation. Emotional prosody is thus part of the linguistic system, at the same time as the lexicon is not separated from other cognitive and communicative abilities, such as understanding and expression of emotional prosody in general.

Chapter 83 - 'Metamorphosis' by Franz Kafka is analyzed in this chapter from a cognitive literary perspective, mindful of recent advances in the field of creative cognition. Employing the 'Wave Method of Cognitive Literature Analysis', a procedural method developed by the writer of this chapter, this chapter displays the importance of social context and agents in the process of transforming fiction from first cognitive impulses of the writer to the final linguistic end product. Calling for a cognitive incorporation of the reader in the analytical process, in what is referred to here as the 'writer-reader dynamic', various linguistic aspects with a solid foundation in linguistic paradigms such as Blending Theory are examined for their impact on the creative spaces of the prototype reader. In doing so, this analysis finds that the 'container' image schema of Gregor Samsa's transformed body is of particular relevance, whilst the extended 'insect' metaphor is found to have varying mental activations depending on agents involved. The assumption of Stockwell that an interaction takes place between texts and humans in the reading of literature is thus built upon in this chapter.

Chapter 84 - The chapter substantiates the concepts of meaning re-conceptualization and approximation in communication as put forward in Lewandowska-Tomaszczyk. The present discussion locates the phenomenon of approximation in cognitive domains and shows the contents of approximative spaces, allowable substitutions in the domains as well as their tolerance threshold, and discusses the circumstances in which this process is evidenced in communication.

Chapter 85 - Many emotional and cognitive stimuli are perceived through the senses, especially through vision. As a result, metaphors mapping to THINKING or EMOTION often incidentally involve PERCEPTION. This does not mean that PERCEPTION is the target domain of the metaphors. In this chapter, the authors present examples from English and Chinese to argue that the role of PERCEPTION in THINKING and EMOTION has led to the miscategorization of numerous metaphors as synaesthetic, when in fact they map to THINKING or EMOTION rather than PERCEPTION. Furthermore, the authors suggest that differences between the domains of THINKING and EMOTION lead to the supposed division between "PERCEPTION IS RECEPTION" and "PERCEIVING IS TOUCHING", and the authors argue against the grouping of these under the heading of PERCEPTION IS CONTACT between a PERCEIVER and a PERCEIVED. This reclassification has the additional advantage of a stricter and more explanatory delineation of the range of metaphors considered synaesthetic.

Chapter 86 - Aphasia is a neurogenic condition while language is not. In the aphasia field, the direction of reasoning should go from brain injury to verbal impairment; the logical implication is one-way. When the logical implication is inverted, the conclusion is false. This principle allows predicting wrong inferences when the reasoning goes in the reverse order. Maybe that was the cause of the impasse suffered on the matter for more than a century and a half. When prospective approaches are not possible, and trying to attenuate the deficits of retrospective ones, then all the patients should undergo the same psychological evaluations. Post-mortem aphasia studies are always retrospective. Curiously, they are still taken as 'definite'. Aphasia patterns have to be discovered independently of their biological basis in

order to avoid circularity; besides, any combination of the latent language impairments has to be recognized. New models concerning the relationship between brain and language have emerged. Beyond the novelty of the instrument used for data collection, deep methodological considerations are necessary not only for discovering the dissociations and interactions among neuropsychological functions, but also for studying the consistency among the different approaches, samples and instruments employed. Nowadays, such consistency has been magnified by dissemination. The impetus to reach consensus with psychological events has led to the shocking situation in which an article published in 1984, for example, has been quoted almost 22,000 times by April of 2015 as synonymous with the procedure for demonstrating diagnosis. Considering the guidelines of 2011 for primary progressive aphasia (PPA) that number was almost 800 in just four years. If the conceptual and the operational definitions are confused, the theory gets into an endless loop. Additionally, the use of typical cases seriously restricts progress. Despite significant improvements observed in the psychological methods during the last years, the psychological outcomes are still puzzling. The ‘comprehension-expression’ organization and the ‘semantics- syntax’ one involve two different systems of classification which are not mutually excluding. Unlike the dissociation between comprehension and expression, the dissociation between semantics and syntax is not easy to observe, even using complex linguistic evaluations. Syntax involves relationships among semantic units but, simultaneously, produces a higher-order semantic unit. Researchers evaluate those levels of ‘semantic’ units to differentiate semantics vs. syntax. The methodology is unclear because changing parts involves changing the whole. Neuropsychology has two parts. If the validity of the psychological outcomes is doubtful, any language neurobiological model will be doubtful.

Chapter 87 - Acquired Childhood Aphasia (ACA) is a medical phenomenon which is still mostly unknown and often disregarded. One reason for this disregard is the rarity of aphasia in children often being emphasized, and the prognosis being assumed to be more favorable for children and adolescents than for adults. Another common reason for the disregard is the lack of understanding the clinical picture of aphasia in children. The provided chapter offers a broad overview of possible definitions, symptoms, prognosis and outcomes of Acquired Childhood Aphasia and the impact on quality of life for the affected children and adolescents and their families. It goes on to show that the prognosis is not as favorable as often proclaimed, and impacts the affected children and their families in numerous ways. Finally, this chapter points out possibilities of therapeutic intervention and provides examples of measures of support for the families.

Chapter 88 - People who develop aphasia must adjust their lifestyle and learn to cope with the activity limitations that result from their disability. Aphasia can profoundly affect a person’s capacity for academic achievement as well as their occupational competency, social participation, and ability to manage finances. This is especially true for young people, who have yet to fully learn how to participate as a member of society. Young people who acquire aphasia are likely to have a poor record at school and have difficulties completing higher education and getting a job. They also might be unable to pass a written test for a driver’s license. Young people with aphasia who wish to contribute to the community and be engaged in social activities might not achieve these goals and might feel isolated. In the worst case, they might shut other people out of their lives and withdraw from society. In this chapter, the authors describe the long-term prognosis of three individuals who became aphasic in their childhood or youth and discuss how young people with aphasia can best be rehabilitated.

Chapter 89 - The concept that aphasia is caused by subcortical lesions dates back to the 1970s. However, this subject is still controversial, even today. Many researchers believe that the cortex is the neural center for cognitive functions, including language, and aphasic symptoms observed after subcortical lesions may result, in fact, from functional impairment of cortical activity. In contrast, other authors have advocated a specific role of subcortical structures in language. Advancements in our understanding have resulted in a change of focus for this issue. The term subcortical aphasia encompasses cases of aphasia resulting from lesions located below the cortex, which includes lesions to the basal ganglia, thalamus, and white matter. Advancements in our understanding of the fascicles that travel over the white matter and that connect different cortical areas related to language have revealed that white matter lesions can produce various changes in language. Thus, to elucidate the role of subcortical structures in language, unique injuries to the basal ganglia and thalamus must be separated from those that affect the white matter. The aim of this chapter is to present evidence for the specific involvement of the basal ganglia and thalamus in vocal production, speech, and language. Hypophonia, difficulties in speech initiation, disfluency, syntactic deficits and semantic-lexical disorders are specifically discussed. Thalamic and basal ganglia lesions seem to accompany more complex deficits of language. As the entire cortex has access to subcortical structures, even Broca's and Wernicke's areas, through cortico-subcortical loops, subcortical structures are predominantly integration structures and thus can participate in different aspects of communicative function. The participation of fronto-subcortical circuits and the integration with the posterior cerebral areas has been proposed. Subcortical structures possibly play an important evolutionary role in language acquisition by humans. Basal ganglia and the thalamus may have adapted its own *modus operandi* for speech functions. The cortico-subcortical network and the interrelationship between corticality and subcorticality should be considered to fully comprehend the function of language.

Chapter 90 - This chapter describes consequences from aphasia from the perspective of those affected and their close relatives. Nine persons with lived experiences of aphasia contribute to data by means of interviews, published books and diaries, and seventeen close relatives narrated about their situation as informal caregivers. All that information was interpreted in three parts in accordance with a lifeworld hermeneutic approach. The first, which dealt with existential consequences of aphasia, indicated that the intentional, non-verbal act when something is recognized *as* something is *not* affected by aphasia. Aphasia merely affects the world of symbols, which is necessary for interaction with others. It is therefore connected with feelings of alienation, inferiority and shame in social settings. The second part, which dealt with the issue of professional aphasia care, suggests that adequate care from the affected person's point of view presupposes a secure base and a caregiver who recognizes and trusts the patient's ability to think and communicate albeit not always verbally. In the third part the investigation is directed to close relative's situation. It is suggested that a life together with an aphasic person means being used as a bridge between the aphasic person and the surrounding world. This leaves close relatives with a lonely burden of responsibility. Finally a synthesizing analyse suggests that aphasia management practice includes care and support as a mutual concern and a shared responsibility for professional carers, close relatives and community service. The principles for that are outlined under seven main heads.

Chapter 91 - From the simplistic explanations of Wernicke's and Broca's, to the latest investigative headways made into the understanding of intricacies involved in the use of the spoken and written words; modern science is still in the process of understanding Aphasia. The use of radiological and pathological diagnostic modalities in the study of language deficits has helped in the recognition of two categories of aphasia. The acute and sub-acute presentations seen mostly in association with cerebrovascular accidents, CNS infections, and head trauma shows involvement of specific parts of the perisylvian language network which is located in the left hemisphere in majority of right as well as left-handed individuals. Based upon the evaluation of spontaneous speech, naming, comprehension, repetition, reading and writing, and diagnostic imaging these aphasia are divided into central aphasia and the disconnection syndromes. The central aphasia, namely Wernicke's and Broca's are due to damage of the two classical, though not anatomically discrete language centers bearing the same names. The disconnection syndromes are a result of damage to areas of the language network other than the classical centers and include Transcortical and Conduction Aphasia among others. The slowly progressive aphasia caused by neurodegenerative diseases are referred to as Primary progressive aphasia (PPA). In order to simplify understanding of these aphasia and thereby help find cures these aphasia have recently been classified into the agrammatic, semantic, and logopenic variants. Management and prognostic issues pertaining exclusively to language disruption are widely studied in the aphasia with actual presentation. The mainstay of treatment is speech and language therapy; however some drugs are also showing promise especially when combined with language therapy. In post-stroke aphasic patients there is a strong correlation between initial severity and eventual recovery. Although most improvement occurs in the first few months, late language therapy has also shown benefit. Ongoing research also points to the potential utility of transcranial magnetic and electric stimulation for the treatment of certain aphasia.

Chapter 92 - Aphasia after stroke is a common and disabling symptom, which can recover in the weeks, months or years following brain injury, showing that the adult brain can reorganize to adjust to impaired functions. Standard rehabilitation approaches aim to improve the deficient function through speech and language therapy (SLT). In parallel with increasing knowledge about central nervous system plasticity, different adjuvant interventions have been recently implemented to enhance the outcome of speech and language therapy. One of them consists in increasing the intensity of SLT in order to obtain better recovery. This is achieved for instance with computer-assisted therapy (CAT) or with constraint-induced aphasia therapy (CIAT) approaches.

A second approach tested the combination of a number of drugs with SLT, with the aim to increase its effect. The mechanism thought to underlie enhanced recovery with the addition of specific drugs includes increasing attention and learning through modulation of neurotransmission or restoring metabolic function. Several substances have been assessed, including noradrenergic drugs and drugs acting on the dopaminergic, glutaminergic, gabaergic, and cholinergic systems.

Finally, another, still experimental, intervention in stroke rehabilitation consists of neuromodulation via non-invasive cortical stimulation, e.g., through transcranial magnetic stimulation (TMS) or direct current stimulation (tDCS). These techniques have recently been proposed to potentially endorse functional recovery after stroke through (i) enhancing excitability of the stroke hemisphere or (ii) suppressing the non-stroke hemisphere to reduce its potential interference with functional recovery of the stroke hemisphere.

While both treatment intensity and TMS have led to several promising results on efficacy in aphasia rehabilitation, the effect of pharmacotherapy seems to be less straightforward. In the present chapter the authors will perform a review of recent literature on the effects of these approaches as potential adjuvant to standard SLT in the rehabilitation of aphasia.

Chapter 93 - Language impairments are frequent in stroke, especially in the hyper acute phase, occurring in 15 to 50% of stroke patients. Recovery from aphasia remains difficult to predict. Language impairment still exists in at least 50% of initially aphasic patients one year after stroke. Post-stroke aphasia is a major source of disability that can lead to impaired communication, reduced social activities, depression and a decreased likelihood of resuming work. The role of the stroke unit in improving morbidity, mortality and recovery has been clearly demonstrated. Nevertheless, the need for intense and sustained acute management of aphasia in specialized stroke units remains controversial. The recent validation of a tool to rapidly screen for aphasia (LAST) after stroke allows for its early detection and management. Early detection of aphasia after stroke may improve outcomes by taking advantage of the synergy between intensive speech therapy and early neural reorganization. Daily re-evaluation will facilitate tailored rehabilitation sessions, multidisciplinary management by the stroke team, and development of educational resources for patients and their caregivers. Standardizing protocols for identifying and managing aphasia requires the co-operation and coordination of the entire stroke team, along with the daily presence of speech therapists. These considerations are crucial for patients in the stroke unit to achieve the full benefit of the management proposed in this chapter, to ultimately promote better long term functional prognosis.

Chapter 94 - In this chapter it is emphasized that there are only two fundamental forms of aphasia, which are linked to impairments in the lexical/semantic and grammatical systems of language (Wernicke-type aphasia and Broca-type aphasia, respectively). Other aphasic syndromes do not really impair language knowledge per se, but rather either some peripheral mechanisms required to produce language (conduction aphasia and aphasia of the supplementary motor area), or the executive control of the language (extra-Sylvian or transcortical motor aphasia). A new classification of aphasic syndromes is suggested. In this proposed classification a distinction is established between primary (or “central”) aphasias (Wernicke’s aphasia—three subtypes—and Broca’s aphasia); secondary (or “peripheral”) aphasias (conduction aphasia and supplementary motor area aphasia); and dysexecutive aphasia.

ABSTRACT

Verbs are the best lexical items to verify the effects of motor learning in language processing. However, compared to nouns, this category has received less attention in studies about lexical disturbances in neurological diseases. Difficulties in verb/action processing have been found in patients with Parkinson's disease, suggesting that frontoestriatal and subcortical areas contribute to the semantic processing of verbs. This finding highlights the possibility of verifying the assumptions of the Embodied Cognition (EC). According to this theory, language processing of action verbs would engage areas involved in planning and execution of the actions represented by those verbs in the motor cortex. The literature in this field has pointed to conflicting results and action/verb cerebral representation, and its impact in language difficulties in Parkinson's disease have been intensively debated. These controversies may be studied in terms of the multilevel

model (Kemmerer, 2014) that predicts that the design of the task will require differential access to the motor features of the verb meaning and that areas related to visual perception, particularly the lateral posterior temporal cortex play a role in semantic processing. The type of task and psycholinguistic variables need to be taken into account since they can measure different levels of semantic processing. In addition, in order to check EC assumptions, studies must contrast distinct types of verbs, for instance action vs. emotional/psychological; biological vs. non-biological; verbs requiring and not requiring tools. Another semantic feature of concern is specificity. Kim and Thompson (2004) distinguish light and heavy verbs and discuss their different speed of deterioration in neurodegenerative diseases. Considering this panorama, this chapter will present, a summary of the different approaches about action/verbs semantics, current debates about verb neural representation and an analysis of the evaluation directed to patients with Parkinson's disease. A Pubmed and Scopus search was conducted in December/2014 using the terms "action verb" OR "verb" OR "verbs" AND "Parkinson's disease" with no time restriction. We retrieved 35 studies and selected 22 for analysis, excluding reviews and studies not related to action/verb semantics in PD. The methodology and findings of those 22 studies were analyzed and contrasted with theories that explain the neural representation of action/verb semantics, in particular the multilevel model and Embodied Cognition accounts. The challenge for new studies is to identify those semantic properties, understand how they are related to cortical processing and develop suitable tools to analyze these features in different profiles of Parkinson's disease.

Keywords: Parkinson disease; multilevel model, embodied cognition, verbs, lexical/semantic processing

INTRODUCTION

Verbs are the best lexical items to verify the effects of motor learning in language, but the study of neural lexico-semantic representations has neglected this category and focused on nouns for a long time. Difficulties in using verbs were described by Pick in 1917 (in Critchley, 1970), and the Neuropsychological interest for this class of words initially concerned their morphosyntactic function. At the last decade of the last century, selective difficulties for verbs and nouns were shown in patients with cerebral focal lesions (Miceli, Silveri, Nocentini & Caramazza, 1988; Caramazza & Hillis, 1991), as well as after the degeneration that occurs in Alzheimer's disease (Kim & Thompson, 2004). The interest on the difficulties to process verb meanings by patients with motor disorders is even more recent and has had implications for the Embodied Cognition theory. According to this theory, language processing derives from experience, and thus the semantic processing of action verbs recruit areas involved in planning and executing those actions in the motor cortex. However, the literature in this area has pointed to conflicting results regarding action/verb cerebral representation and its impact on language difficulties in motor disorders such as Parkinson's disease.

This chapter has the purpose of discussing the results of a systematic review about action/verb processing in patients with Parkinson's Disease (PD), presenting the current panorama in this area of research. Before addressing the pathology, however, we will present the set of studies that made scientists draw their attention to the production of verbs in PD. First, we will describe some important concepts about the semantics of verbs. We follow with

a brief history of the theoretical landmarks, which promoted interest in the study of neural representations of verbs and the current controversies. Finally, we present the results of our systematic review and analyze the methodologies and main findings of 23 recent studies for a critical discussion of the neural representation of action/verb semantics in terms of the strong and weak versions of the Embodied Cognition theory. In this context, we emphasize the contribution of multilevel models to interpret the controversial findings of the studies. We focused on the semantic processing elicited by different tasks and the points to be considered in future research.

THE SEMANTICS OF VERBS

Verbs and nouns present many syntactic and semantic differences. These systems require distinct mechanisms: while the lexical-semantic system is based on declarative memory, the syntactic system corresponds to procedural memory (Ardila, 2012). In addition, verbs have a unique syntactic role; they act as the center of a sentence, linking the other elements.

In the semantic level, when compared to nouns, verbs represent actions and “relational” concepts (Gentner, 1981), while nouns refer to objects or events. Also categorization differs between the two grammatical classes. Hierarchical models propose that nouns are categorized according to the group they belong (i.e., *elephant* is a wild *animal*, big, and has a trunk, etc.), answering to a question “WHAT IS IT?” (Rosh & Mervis, 1975). Verbs are categorized according to HOW the action is held (i.e. *running* is *walking fast*) (Miller & Fellbaum, 1991).

Kim and Thompson (2004) proposed a hierarchical categorization of verbs based on higher or lower levels of specificity. On the top, we find “light verbs”, those who have little semantic information, but an important syntactic role (i.e., *can*, *to be*, *to do*, etc.). Then, generic and specific verbs, which possess richer semantic information associated with their meanings. Specific verbs are more complex and demand more cognitive resources in their processing, e.g., *to run* is semantically more complex than *to walk*, because *to run* is one of the possible ways *to walk*. Thus, semantically simpler verbs – the generic verbs – can be used in broader contexts, whereas semantically more complex ones – the specific verbs – are used to refer to more restrictive actions. For instance, the action represented by the verb “*to cut*” can be held in different ways: with a knife, with the hands, with a scissor, etc. while “*to saw*” is held in only one way and requires a tool.

Specificity is an important feature in language processing. This was evidenced both in lexical development and in language deterioration. Older children use more fluently specific verbs (Tonietto, Parente, Duvignau & Gaume, 2008), while in Alzheimer's Disease and Semantic Dementia, the occurrence of generic verbs is higher (Kim and Thompson, 2004; Méligne et al., 2011).

Another semantic classification was proposed by Levin (1993), which considered syntactic and semantic features. In an exhaustive study of the English language, the author found more than 200 verb classes, all of which can be grouped as similar in meaning. Many studies in Neuropsychology and Neuroscience of Language used this classification, usually employing some of the proposed categories to generate assumptions on their neural correlates, which depend on the semantic properties of the verbs. For instance, in action verbs research, Kemmerer (2008), used fMRI to record brain activity elicited by five broader

categories: Running (e.g., *to run, to walk*), Speaking (e.g., *to whisper, to yell*), Hitting (e.g., *to hit, to poke*), Cutting (e.g., *to cut, to slice*) and Change of State (e.g., *to crack, to smash*). In this study, verbs were classified according to their semantic features: ACTION, MOTION, CONTACT, and TOOL USE, and the author held a neuroanatomical prediction to verify whether semantic knowledge is grounded in sensorimotor systems, the basis for the Embodied Cognition approach, detailed below. Kemmerer (2008) highlighted the variability of these classifications according to the semantic structure of a language and the need of cross-cultural studies.

Thus, we have a hierarchical model of verbs' categorization concerning the level of semantic specificity and verified both in language development and in its dissolution due to different forms of dementia processes. However, the order in which specificity facilitates neural processing, as well as how it affects verb processing in patients with motor degenerative disorders has not yet been studied. On the other hand, anatomical hypotheses were postulated from the syntactic-semantic features of verbs and the development of those models was only possible due to the evolution of Cognitive Neuropsychology, detailed below.

THEORETICAL MODELS THAT PROMOTED THE VERBS NEURAL REPRESENTATION STUDIES

The recent increase of studies focusing on neural correlates of verb processing and their difficulties depended on the theoretical evolution of Cognitive Neuropsychology. In this field, language is considered a complex activity, which involves different mental processing. In an initial period, the models used a computational metaphor or a hypothetical neural connexionism, and the modularity notion proposed by Fodor (1983). In this modularity proposal, language, as other cognitive functions, was seen as an "encapsulated" process, and thus, could only be studied separate from other functions. Computational models were replaced by the so called "Cognitive Revolution", led by Bruner (1986). This revolution replaced *meaning* by *representation*, and so, language became the center of human cognition. A decade later, language studies turned to integration to other systems, as working memory and attention (e.g., Gathercole & Baddeley, 1993).

Despite the interaction between different cognitive functions, language was still analyzed separately from other systems. The semantic knowledge was considered as an organization of abstract concepts and, thus, independent from sensory-motor processes. Furthermore, besides recognizing memory and attention interferences in language, this theory (nowadays known as *amodal* theory), does not consider the body as a participant of semantic knowledge.

A new proposal on acquisition and development of psychological capacities arises from Embodied Cognition theory (EC) (Shapiro, 2011). This approach proposes the integration of perceptual, linguistic, and motor functions when trying to understand internal, as well as external, individual phenomena. From this associative perspective, such information processing can recruit adjacent areas even if these areas are specialized in other functions (Wilson & Foglia, 2011). Linguistic processing approximates *meaning* to the real object or action, and language is no longer understood as an abstract representation of the world.

The EC returns to Wittgenstein's (1953) ideas that propose that lexical learning is directly related to the individual interaction with the world. Thus, to EC the subject associates the meaning of the actions that he performs and the objects with which he interacts to the description of those given by the external world, integrating movement, perception, and language. Thus, the body is seen as the cause or condition for cognitive constitution, establishing an interdependent relation between processing and bodily relation with the world. Therefore, verbs are the lexical items per excellence to verify the effect of motor learning through language (Shapiro, 2011; van Dam, Rueschemeyer & Bekkering, 2010; Barsalou, Simmons, Barbey & Wilson, 2003).

The mirror neuron theory supports EC theory (Kohler, Keysers, Umiltà, Fogassi, Gallese & Rizzolatti, 2002). The former, through studies with apes, postulates that when observing an action and/or planning it, motor and premotor cortices are activated, respectively. In the language field, linguistic learning results from experience with the external world, and therefore semantic processing of action verbs, would activate the same motor and premotor cortices. Therefore, to EC theory, holding, observing and describing an action would evoke the same neuronal apparatus, in other words, when we say the word “walk” the mental homunculus actually moves (Pulvermüller, Härley & Hummel, 2001; Barsalou et al., 2003).

However, EC findings are not supported by all experimental data and those controversies favor the maintenance of explanations in terms of the amodal model. This model, as said above, postulates that the words' meanings in the lexicon are independent from perceptual inputs and motor outputs. The debate between these two positions (i.e., EC and amodal model) promoted the advancement of the current knowledge about neural representation in healthy subjects and motor system pathologies, as well as the proposal of a conciliating approach: the multilevel model (Kemmerer, 2015). Thus, before analyzing the studies of verb processing in patients with Parkinson's disease we will present, in the next section, a brief panorama of the discussions of neural correlates of action/verb processing.

CONTEMPORARY MODELS ABOUT NEURAL VERB REPRESENTATION

Firstly we will explore some of the work that, based on the EC theory, find verbs activating motor areas (primary motor cortex M1; precentral gyrus and several premotor cortex areas) or areas responsible for movement perception (posterolateral temporal cortices - PLTC and Middle temporal area MT+). This approach is called strong Embodied Cognition position. Then, we will illustrate some of the work of the authors that defend that concepts of verbs are independent from movement representation and modality-specific regions, and instead organized, according to semantic aspects of verbs, the amodal model. Lastly, we will present the multilevel model, a weak version of the EC theory.

Strong Embodied Cognition Position

The idea that verb processing is different from noun processing arises from double dissociations found in studies with aphasic patients (for a review see Vigliocco, Vinson, Druks, Barber & Cappa, 2011). Studies of focal neurological lesions have shown that the

lexicon is represented by different neuronal networks through grammatical word differences: anterior frontal areas would be responsible for verbs representation and temporal areas, for nouns. However, recent studies with patients with cerebral focal lesions have shown that verb processing demands a large neural network, and thus it is unlikely that clear separate areas for nouns and verbs exist. Kemmerer, Rudrauf, Manzel and Tranel (2012), proposed six different tasks requiring expression, comprehension and semantic similarity judgments of verbs, and evaluated 226 brain damaged patients using this set of tasks. Sixty-one patients had difficulty in one or more tasks; four had difficulties in all tasks and the rest had a complex dissociation and association between tasks. Despite the left hemisphere predominance of the difficulties, an extensive neural net was found to be related to these deficits: the inferior frontal gyrus; the ventral precentral gyrus, extending superiorly into what are likely to be hand-related primary motor and premotor areas; and the anterior insula, the ventral postcentral gyrus; the supramarginal gyrus; the posterior middle temporal gyrus. The authors concluded that their results confirmed EC's postulates.

Shapiro et al. (2005), tried to replicate the findings of double dissociation in aphasics in an experiment using PET scans with healthy participants. The findings of that study also showed prefrontal cortex activation in verb processing, while temporoparietal areas bilaterally were activated in processing nouns.

Trying to specify the relationship between language and motor functions, from EC theory, Pulvermüller et al. (2001) hypothesized that associative learning – also called semantic learning – recruited the neuronal network responsible for bodily movements for mouth, hand and leg actions. Mouth action verbs would be represented cortically in a more restricted area in the inferior frontotemporal region; hand-action verbs, in inferior and medial frontotemporal areas; whilst leg-action verbs would have a more extended processing, involving superior frontal sites.

The studies that used fMRI technique to address the semantics of verbs, having support of Pulvermüller's associative theory, found, as expected, representation of mouth-action verbs in the inferior prefrontal gyrus (Hauk, Johnsrude & Pulvermüller, 2004; Tettamanti & al, 2005; Azzis-Zadeh, Wilson, Rizzolatti & Jacobini, 2006; Rüschemeyer, Brass & Friederici, 2007), or in the posterolateral temporal cortex (Kemmerer, Castillo, Talavage, Patterson, & Wiley, 2008). When leg-related action verbs were studied, the majority of findings pointed to activation on the prefrontal or superior frontal motor area, which coincides with the homunculus motor representation (Hauk et al. 2004; Tettamanti et al, 2005; Kemmerer et al. 2008), except for the findings of Azzis-Zadeh et al. (2006), which showed a prefrontal medial activation to movements. However, neural representation of movements held by the hands still present contradictory findings. Azziz-Zadeh et al. (2006) found that hand's and leg's representations overlap, which contradicts the assumptions of the somatotopic theoretical model.

Specifying the semantics of verbs held by hands, Kemmerer et al. (2008) showed that, in distinguishing movements of clapping hands from cutting with hands, the former activated superior motor areas and the last ones, medial premotor and temporal and frontoparietal network. To these authors, the presence of premotor areas is justified by a higher demand on planning skills, since the vast majority of cutting verbs need tools. Moreover, Yang, Shu, Bi, Liu & Wang (2011), taking advantage of the uniqueness of the Chinese writing, designed an experiment with 3 stimuli groups: (1) hand verbs containing hand root; (2) tool verbs containing tools root; and (3) tool verbs containing hand root. They found that all verbs

elicited left medial frontal cortex and left inferior parietal activations and, activation on the premotor region was found for all conditions when subtracting hand movements in the analysis. Tool verbs, as in a previous study, presented higher connectivity, with frontoparietal representations and activation of the posterior temporal cortex. The authors interpreted this dispersion as evidence of higher semantic processing demands to accomplish the complex task of verb comprehension involving tools. Despite the quite interesting experiment design, focusing on Chinese writing aspects, which implicates a hand or an instrument symbol, the results may be biased by the fact that the writing of these roots gives extra implicit information.

Besides motor areas, verb comprehension also recruits the temporoposterolateral cortices (PLTC and in the left middle temporal gyrus (LMTG)). The pioneer study, showing that the LMTG activation related to verbs, was published by Martin, Haxby, Lalonde, Wiggs & Ungerleider (1995). Later, several works showed that this activation occurs in different tasks, such as generation of action verbs, semantic relatedness judgments, and semantic triads. Moreover this activation was found in different languages using as stimuli different types of verbs, as action verbs and mental state verbs (for a review see Bedny & Caramazza, 2011). PLTC is close to the middle temporal area (MT+), a brain region that processes movement of animate beings. Despite the debate regarding the function of the PLTC in verb processing, this area in the left hemisphere presents greater responses to motion-related than non-motion related verbal descriptions (Tettamanti et al., 2005). Thus, for the authors that support the strong position of EC, the activation of those areas subserve a high-level motion perception (Kemmerer, 2015). However, a great amount of the work designed to address the strong EC position has problems in controlling stimuli regarding psycholinguistic variables and in analyzing the processing demands of the task. Neuroimaging studies show a joint activation for verbs and nouns, indicating that semantic representation of words (nouns or verbs) rests on lexico-semantic traits (or psycholinguistics criteria), such as concreteness (Lee & Federmeier, 2008), frequency (Vigliocco, Vinson, Arciuli & Barber, 2008) and ambiguity (Lee et al., 2008; Li, Jin & Tan, 2004).

On the other hand, controversial findings on the neural representation of hands' movements may be explained in terms of the use of these verbs. Hand actions are developed only in superior mammals, and in the humankind they present vast semantic variability. It is probable that this diversity in hand actions have biased the tasks. For instance, in the experiment designed by Pulvermüller et al. (2001), there are verbs that denote very specific movements, as *to box* and others, very generic as *to beat*. The neural differentiation of objects and verbs, when taking into account the concreteness criterion, which distinguishes action verbs from mental/psychological verbs, is already known (Crepaldi, Berlinger, Paulesu, & Luzzatti & et al., 2011), but so far, we haven't found studies about neural organization considering verbs' specificity, which classify action verbs in generic and specific verbs.

The importance of psycholinguistic factors on brain processing was shown by Hauk, Davis, Ford, Pulvermüller e Marslen-Wilson (2006). Through a regression analysis of electrophysiological data, they showed that the time course of processing of the lexicon psycholinguistics features varies. Their results suggest a bottom-up processing in lexical decision tasks, in other words, the visual aspects, as word extension, are detected early in time, followed by word frequency, and the semantic aspects are processed later in the brain. It is worth noting that this work used nouns whereas the time course of different lexical aspects of verb processing has not been studied yet.

Lastly, task complexity can influence experimental results. Tasks that demand higher cognitive resources favor noun/verb dissociation, stressing the role of executive functions and working memory (Cappa, 2012; Cristescu, Devlin & Nobre, 2006). Thus, differences found between psycholinguistic features and neural correlates indicate the need to control the morphosyntactic and semantic variables between the grammatical groups (nouns/verbs) and a carefully design the experiment, choosing an adequate task, which is fundamental to analyze the activation pattern (Cappa, 2012).

The Amodal Model

Strong criticisms of experiments that defend EC theory come from researchers that support the amodal model. This model postulates that semantic representations are accessed independently from the modality of the stimuli. This theory starts with many experiments focusing on nouns, and only later focused on verbs semantics. Even if there is a small number of works focusing the semantics of verbs, they had great repercussion in the debates about neural representation of verbs.

The main postulates of this theory are: (1) if the same brain area is activated by different modalities when concept is presented (oral, written words or figure presentation), it is possible to conclude that this brain area represents that conceptual knowledge is supramodal in nature; (2) the overlapping of brain areas when activated by different tasks does not mean that the same mechanism is involved, and lastly, (3) the amodal theory defends that it is not possible to know whether rapid processing of motor areas involved in verb comprehension is the cause of semantic comprehension of these verbs or a consequence of retrieving semantic knowledge (Mahon & Caramazza 2008; Caramazza, Anzellotti, Strnad & Lingnau).

To verify if the same brain areas are activated by different presentation modalities of a concept, Fairhall & Caramazza (2013) designed an experiment in which subjects performed a typicality rating of one item within its category. Nouns of five semantic categories were: tools, clothes, fruit, birds and mammals. Different blocks presented the written word or its picture. Using Representation Similarity analyses (RSA) they found that two brain regions, the posterior middle/inferior temporal gyrus (pMTG/ITG) and cingulate/precuneus (CP) responded in a similar way to all categories.

In another study, Wei et al. (2013) used living (animals) and artifact categories in three different tasks (object picture-naming task, object picture associative-matching task; object sound-naming task), and non-semantic tasks as control. Through a regression analysis, the authors observed that the LMTG was the core component that accounted for 74% of the semantic processing performance variation only on semantic tasks and not on number processing, which is a non-object-concept task. The authors conclude that the LMTG is the core of a network that undertakes the conceptual processing for nouns. Furthermore, Bracci Cavina-Pratesi, Ietswaart, Caramazza and Peelen (2011) have shown that the lateral occipital temporal cortex responses to tools overlapped with hand responses, but not with other object categories. They proposed a high-order semantic function in the visual cortex.

Bedny et al. (2008) designed an experiment to verify whether the activation of PLTC is due to sensory-motor features of verbs or, in an alternative interpretation, if these activations result from a modality independent processing. They elaborated an experiment of semantic judgment of varying pairs of verbs, regarding the amount of motion information. As expected,

higher activation in PLTC were obtained with verbs when compared to nouns. Moreover, the verb's advantage was independent of the amount of motion, that is, action and abstract verbs obtained higher responses than nouns. The authors claimed that the PLTC is responsible for the retrieval of events. Conceptual properties of the events are organized according to their semantic aspects and do not involve the sensory-motor experience.

This study compared neural activations between normal seeing individuals and congenitally blind ones. It caused a big impact and supported amodal position, verifying whether visual experience influences the semantic processing of verbs. Bedny and Caramazza (2011) tested the hypothesis that the LMTG modulates representation of motion of verbs, and thus whether verb concepts are grounded in a sensorial representation of the motion. They compared sighted and blind subjects in verb processing. Following the authors, if the EC hypothesis is true, the LMTG would be altered in those who had never seen. The study showed that the LMTG was equally engaged for nouns and verbs and that the same profile was found in congenitally blind individuals. For the authors, those results showed that LMTG storage concepts are independent from the subjects' experiences and, therefore, do not depend on its visual representation. However, it is possible that this region stores some kind of movement representation, which, in sighted individuals, has a visual aspect.

Even with radical oppositions to the EC, the authors consider that “although the neuroanatomical data suggest that word comprehension is supported by modality-independent representations, there is also wide evidence that language, perception, and action are not isolated modules, but rather interact dynamically” (Bedny & Caramazza, p. 92).

The Multilevel Model

Kemmerer (2015), in the context of EC or Grounded Cognition, proposed a model according to which the meanings of action verbs would recruit precentral motor areas, but not *always* neither in a *fast* or *automatic* fashion. Recruitment of motor areas would vary according to the demands of the task and would not be always necessary for comprehension. Instead, it would happen only when motor simulations were needed to process meanings. In addition, depending on the context or type of verb, the lateral posterior temporal cortex would also be activated to allow visual perceptual processes that would enrich the semantic representation or attempt to complete it in order to compensate deficits in patients with diseases affecting the motor system (Kemmerer, 2012).

Despite neurophysiological evidences in healthy subjects, which favor the strong version of the EC account, findings with patients presenting diseases affecting the motor system have not been entirely consistent with its assumptions (for a review see Silva et al. 2014). Therefore, the multilevel model proposed by Kemmerer (2015) is a conciliating alternative and manages to explain some of those controversial findings. This model has two important advantages: (1) it explains the absence of a dramatic language deficit in verb/action processing, predicting that motor simulation is optional rather than necessary; (2) it contributes to the description of the underlying mechanisms to compensate for action/verb semantic deficits, and explains the variability of behavioral results among patients with motor diseases.

The multilevel model brings some elements of the neurobiological model of semantic processing proposed by Binder e Desai (2011), i.e., the assumption that the demand on

sensorial and motor simulations is quite variable in several modalities for comprehension (e.g., spontaneous oral language, object recognition, reading). For example, given the speed of spontaneous oral language it would be unlikely that all the content was fully processed with simulation or re-experience of motor, sensorial and emotional aspects. In that situation, abstract schemes or concepts, whose nature is not modality specific, would be accessed quickly and manipulated for communication, demanding nothing or almost nothing of visual imagery or motor simulation. On the other hand, situations in which unfamiliar/infrequent sentences are employed or where specific lexical elements are inserted would require access to the complete semantic representation, including perceptual and motor areas as well as emotional ones (although empirical evidence on the latter is scarce as they have been neglected by most studies in this theme). In sum, in Kemmerer's account the higher the familiarity and the amount of contextual information, the less necessary it is to access detailed representations in modality specific systems.

Kemmerer's model proposes that knowledge has a flexible architecture in which low level systems (specific modality - for action, perception and emotion) and high level systems (multi- and cross-modal) denominated *hubs* have different roles in semantic processing. The author incorporates to his model the assumptions of the Hub and Spoke framework (Pobric, Jefferies & Lambon Ralph, 2010). That model has empirical evidence from patients with semantic dementia (or semantic variant of primary progressive aphasia) whose main symptom is a progressive difficulty to process word/object meanings affecting comprehension and expression (severe anomia) and that correlates with progressive atrophy of the temporal poles bilaterally. The Hub and Spoke model (Pobric, Jefferies & Lambon Ralph, 2010) considers that the anterior portions of the temporal lobes are critical centers for semantic processing and that they are modality-invariant or amodal, whose function is "binding together the cortically distributed sensory and motor features of concepts; organizing those representations so that the boundaries of concepts are delimited more or less precisely, thereby allowing individuals to efficiently judge category membership" (Kemmerer 2014, p.322). It is worth to highlight that the idea of a semantic hub, though quite defined in the literature, is not consensual. For instance, Binder and Desai (2011) reject the notion of a single semantic hub and support that depending on the nature of the information, other areas would also work as hubs. The temporal pole would be a hub for static semantic knowledge (integrating information to the "what" route) whereas the parietal inferior lobe would integrate semantic aspects related to events (to the "where" route). These aspects still require empirical evidence, however, both hub models (unique or multiple) argue in favor of the hypothesis that semantic knowledge access may not necessarily involve the activation of specific modality areas (spokes) and that a weaker version of EC would be more appropriate to explain the findings in patients with diseases that affect the motor system.

Another issue of debate is the number of spokes and the modality specific information processed by them. In Kemmerer's model, two spokes are highlighted, one with motor features of the verbs (in motor areas/precentral cortex), and another that process visual motion features/high level motion perception.

According to the author, part of the semantic processing of action verbs would require implicit and automatic retrieval of different types of visual movement patterns (similar to the activation of motor patterns proposed by the strong version of EC). In his work with brain damage, these visual patterns recruited the posterolateral portion of the left temporal lobe in all the categories of verbs he studied (Kemmerer, 2015). The author recognizes, however, that

the activation of these areas could also reflect post-comprehension visual imagery or also more abstract perceptual aspects, since his findings could not be conciliated with the aforementioned ones of Bedny et al. (2012) and that support the amodal theory. Bedny et al. analyses indicated that the left PLTC responded significantly more to verbs than nouns, regardless of the amount of motion conveyed by the words, and regardless of whether the subjects were sighted or blind.

Now, we turn to the question of when and how these features (motor and perceptual) would be accessed for the semantic processing. For that, in the following session we analyze the findings of the systematic review in verb/action semantics and PD.

VERB DIFFICULTIES AND EC ACCOUNTS IN PARKINSON DISEASE

PD is a neurodegenerative disease characterized by bradykinesia (slowness of movement), rigidity, tremor, gait, and posture problems. It is caused by a progressive loss of dopamine in the nigrostriatal tract, reducing the projections of the basal ganglia to the frontal motor regions. The deficits in the dopaminergic pathways cause hypo-activation of the supplementary motor area and primary motor cortex, and hyper-activation of the ventral premotor cortex, reflecting a compensatory mechanism (Kemmerer et al., 2013; Cardona et al., 2013). PD is an interesting framework for investigations on the role of the frontal network in the Semantics of verbs due to the possibility of exploring, in the same patient, the ON and OFF effects induced by medication (Levodopa) and by Subthalamic Nucleus (STN) stimulation. In a recent review, we summarized the findings in this area and discussed their contributions to support the Embodied Cognition theory (Silva et al., 2014). Here we update the literature review in order to discuss controversial findings in terms of cognitive demands and different approaches of cognitive models that explain semantic memory processes.

A Pubmed and Scopus search was conducted in December/2014 using the terms “action verb” OR “verb” OR “verbs” AND “Parkinson’s disease” with no time restriction. We retrieved 35 studies and selected 23 for analysis, excluding reviews and studies not related to action/verb semantics in PD.

As shown in Table 1 the tasks used to study verb processing in patients with Parkinson’s disease used several different tasks: spontaneous conversation, naming picture; word generation, verbal fluency; lexical decision tasks; imagery, go/non/go task; semantic judgment tasks and action compatibility effect (ACE).

Free Oral Conversation

One of the postulates of the multilevel model is that more automatic tasks would not always require motor regions for semantic processing, and thus we would expect that the use of verbs in spontaneous conversation would not be affected in PD. That was the finding of Nikumb (2014), which to our knowledge was the only study to explore the semantics of verbs in natural conversations. The author recorded conversations and compared PD patients and controls (spouses) regarding the mean number of verbs produced per minute.

Table 1. Tasks used to study verb processing in patients with Parkinson's disease

Study	Task	Performance of PD Group Relative to CG	PD Group ON or OFF State/ DBS ON or OFF State
Nikumb (2014)	Free oral conversation	Participants with PD produced significantly fewer high-motion verbs compared to low-motion content verbs. However, control participants also produced significantly fewer high-motion verbs compared to low-motion content verbs. T	Not applied.
Letter et al. (2012) (EEG)	Passive Reading	Not applied.	In ON the differences in density currents were found to be larger in left-hemispheric areas than in the right-hemisphere. Activation of motor, pre-motor and parietal areas was lateralized according to clinical motor signs.
Silveri et al. (2012)	Passive Reading	No interaction between grammatical class and group was observed. PD patients were slower but as controls whereas accuracy had ceiling scores for both groups.	No effect of DBS ON and OFF state.
Bertella et al. (2002)	Naming	A noun/verb dissociation with a relative verb deficit was found in patients affected by PD	Not applied.
Cotelli et al. (2007)	Naming	PD patients were more impaired in action naming than in object naming. Manipulability factor was not significant.	Not applied.
Rodríguez-Ferreiro et al. (2009)	Naming	PD patients presented a significant impairment in action naming compared to object naming, whereas healthy participants and Alzheimer disease patients did not have differences.	Not applied.
Herreira, Rodríguez-Ferreiro & Cuetos (2012)	Naming	Not applied.	RT differed for high and low motor content pictures in PD patients off medication, compared to the same patients.
Silveri et al. (2012)	Naming	PD group had poorer performance (accuracy and reaction time) on naming nouns and verbs than healthy control group. Significantly worse performance was observed in PD. In DBS OFF state patients had less accuracy as compared with controls in naming actions, but not for objects.	PD patients were significantly more accurate and faster in the DBS-ON stimulation condition in both object and action naming. Differences in DBS ON x OFF were observed for verbs. PD DBS-ON patients had fewer anomias and semantic errors in naming actions. No correlation of naming performance and memory and executive functions was observed in PD group

Study	Task	Performance of PD Group Relative to CG	PD Group ON or OFF State/ DBS ON or OFF State
Nguyen et al. (2013)	Go/no Go task	An interaction was found between PD dominance and upper and lower limb verbs. Patients with greater upper limb deficit were slower in answering upper limb than lower limb verbs. However, patients with lower limb greater deficits did not show differences in responding to upper and lower limb verbs.	
Herrera, Cuetos & Rabinboca (2012)	Verbal fluency - phonological, semantic and action fluency.		T Differences in the total of words produced were observed in both the phonological and action categories between PD OFF/ON and PD OFF and healthy controls. There were no significant differences between PD patients ON medication and controls. Relative to frequency of words, PD OFF emitted words with higher frequency in action fluency than healthy control group.
Tomasino et al. (2014)	Lexical decision	Not applied.	Results pointed that accuracy not differed between groups. RT for action-related verbs was significantly faster for positive than negative commands in the DBS-ON, while they were identical in the DBS-OFF 50%
Fernandino et al. (2013a)	Lexical decision associated with priming effect and judgment task	Lexical decision task showed faster reaction time for both groups for hand-action verbs than for abstract verbs. Prime effect difference was not observed. In judgment task action verbs responses were slower than for abstract verbs	
Boulenger et al. (2008)	Lexical decision associated with priming effect		During OFF state of dopaminergic treatment no priming was found for action verbs, whereas recovery was found during ON state. Concrete nouns were not affected by the dopaminergic treatment.
Péran et al. (2003)	Generation task	Patients had the poorer performance for verb-verb and noun-verb generation but similar performance on noun productions. Patients had more grammatical errors in three tasks involving verbs. Significant negative correlation between performances on the condition that required a switch between category, i.e., noun/verb condition and Dementia Rating Scores	Not applied.

Table 1. (Continued)

Study	Task	Performance of PD Group Relative to CG	PD Group ON or OFF State/ DBS ON or OFF State
Castner et al. (2008)	Generation task	PD participants, regardless of Subthalamic Nucleus (STN) stimulation condition, produced more errors in the verb–verb condition	Semantic attribute of probes (visual or motor features) did not relate on response errors for PD participants (in the ON and OFF) and controls. In the PD ON stimulation condition, selection constraint (ratio of selection of words) was significantly correlated with mean error in the noun–verb condition and verb–verb condition
Crescentini et al. (2008)	Generation task	In noun generation, strong associations between stimuli and responses led to better performance in the PD group in this task. Relative to verbs, PD patients were significantly impaired in all conditions of verb production in comparison to the control group. PD patients made significantly more grammatical errors and no-response errors. Executive functions in PD group were associated with errors in verb generation.	Not applied.
Péran et al. (2009) (fMRI)	Generation task	No differences were observed between types of substantives, but relative to generation of actions. No correlations were observed between performance and UPDRS and cognitive scores. In fMRI data, severity of disease was associated with action generation in bilateral post-central girus, left operculum frontal area, left supplementary motor area and right superior temporal cortex.	Not applied.
Péran et al. (2013) (fMRI)	Generation task	Not applied.	Generation of action had more errors than Object naming (ObjN). GenA elicited significantly more activation than either ObjN in left prefrontal cortex, left middle precuneus. MSoA showed significantly more activation than ObjN in the prefrontal cortex bilaterally and in the parietal–occipital junction bilaterally. ON>OFF for [GenA vs ObjN] contrast showed mainly premotor areas and for [MSoA vs ObjN] thalamus and premotor areas. However, differences between OFF> ON did not show significant differences.

Study	Task	Performance of PD Group Relative to CG	PD Group ON or OFF State/ DBS ON or OFF State
Herreira & Cuetos (2012)	Generation task	PD OFF, ON and performance of control group were compared.	PD patients OFF medication said words less associated with the target compared with when they were on state. In the OFF state patients generated less semantic related responses for verbs than control groups, while PD ON have the same performance than controls. No differences were observed for nouns between PD OFF or PD ON and healthy controls.
Fernandino et al. (2013b)	Lexical/semantic processing of phrases	Patients, but not controls, were slower to respond to literal and idiomatic action than to abstract sentences. Groups did not differ in accuracy levels.	
Fernandino et al. (2013a)	Semantic similarity judgment	Accuracy was significantly lower for PD patients than for controls, while RT did not differ between groups. In PD group accuracy in the action condition was lower than in the abstract condition.	
Kemmerer et al. (2013)	Semantic similarity judgment	There was no effect of group, indicating that PD patients have the accuracy of control group. RT of action verbs and no-action verbs did not differ between groups.	Patients failed to respond to significantly more items in OFF condition than in ON. PD ON and OFF have the same accuracy. In RT, differences were in Cutting x Hitting in PD OFF < NC and PD ON < NC. RT for change of state were longer than psych verbs in PD ON < NC and PD OFF < NC. Non-parametric correlations were observed between PD OFF – duration of disease and accuracy in cutting and psych verbs.
Ibáñez et al. (2013)	Action Compatibility Effect	PD presented only differences in RTs in the neutral trials compared with compatible and incompatible trials. There was no ACE effect in PD group, in opposition of control group data. KDT accuracy was highly associated with the ACE. A negative correlation between hand-KDT error trials and the ACE.	Not applied.

Moreover, the occurrence of high- and low-motion verbs was quantified. No quantitative and qualitative differences were found between patients and controls. All subjects produced more low-motion verbs and no deficit was found in the PD group in this task when compared to the control group. Although the multilevel model prediction is that the degree of motion would affect the performance of patients with motor diseases, the degree of automaticity of the task could have facilitated the use of verbs by PD patients.

Reading Tasks

Reading can be classified as automatic processing, mainly for very frequent words and when the irregular grapheme-phonemic conversion requires a direct access to semantics. Letter et al. (2012) evaluated 7 PD Dutch patients through a silent reading task associated to EEG recordings and LORETA analysis and compared ON and OFF Levodopa states. The stimuli consisted of thirty hand-action verbs and 30 non-action verbs and the authors used a subtraction method to study the neural correlates of action verbs. Ten regions of interest were analyzed and consisted of five homolog pairs in each hemisphere: Precentral (premotor) cortex; Inferior frontal cortex, Dorsolateral prefrontal cortex (DLPFC), Superior temporal cortex and Inferior parietal cortex (part of the supramarginal gyrus). Higher current densities were found in the on-state as compared to the off-state in all evaluated brain areas and for some patients activation was lateralized according to clinical motor signs. Given the nature of the task and neuroimaging data, these results support the strong version of the EC theory. However, a limitation of this study is that the sample was quite small.

Silveri et al. (2012) investigated the impact of Deep Brain Stimulation (DBS) in a reading aloud task of nouns and verbs. The authors evaluated 12 PD patients that were instructed to read the words aloud as fast as possible. No differences were found between ON and OFF states. Moreover, a ceiling effect for reading accuracy was observed both for nouns and verbs, and PD were slower than controls in both grammatical categories. The results are discussed in terms of executive demands of the task. The authors propose that PD implies in an executive dysfunction, which impairs active lexical search as they find differences in naming (discussed below) but not reading. Another interpretation could be that the grapho-phonemic processing in reading a regular written system, such as Italian, could reduce the semantic processing of the verbs. Also it is possible that the Reading task was extremely simple for both groups and the greater RT obtained by the PD patients could be due to their motor limitations. Moreover, in this study, the major limitation is that it compares nouns to verbs instead of different verb categories.

The two studies that used reading tasks seem to present opposite results. It is difficult to compare them only regarding the task, since one required silent reading and the other reading aloud. Differences in their design could also have influenced the results. The former compared ON and OF Levodopa states and the latter DBS stimulation effect, thus their main objective was to verify treatment approaches.

Naming Tasks

Although a formal task, naming can also be considered an automatic procedure, since it is frequent in daily conversation and does not require complex semantic processing. Except for Herrera and Cuetos (2012) who investigated naming of high and low motion action verbs, the four other studies analyzed noun/verb differences. Two of these noun/verb studies (Bertella et al., 2002 and Cotelli et al. 2007) found a disproportionate deficit for verbs compared to nouns. Bertella suggested that their findings show the role of fronto-striatal system in verb processing, which could be in accordance to the EC model. However, Cotelli et al. (2007), besides noun and verbs comparison, tested the influence of a semantic attribute - manipulability (the involvement of fine hand movements), and found that performance of PD patients was not influenced by this feature but instead by the grammatical class of the stimuli, which would be in favor of the amodal model claim. However, manipulability was assessed in nouns and verbs (i.e., objects which can or cannot be manipulated and actions that do or do not involve fine hand movements), which may limit the interpretation of this finding.

Silveri et al. (2012) did not use a control group, but instead investigated On and OFF DBS effects. Only action naming was impaired in the OFF state and the findings were explained in terms of grammatical class differences and cognitive demands of the task. Silveri et al. used naming and reading tasks and found that only the former was impaired in PD. Therefore, their finding could also be explained according to the weaker version of EC.

The other two studies (Rodríguez-Ferreiro et al., 2009 and Herrera and Cuetos, 2012) compared PD patients' performance to healthy adults and Alzheimer's Disease (AD) patients. Rodríguez-Ferreiro used the classical verb/noun comparison and interpreted the verb difficulties in terms of the EC account. PD patients presented a significant impairment in action naming compared to object naming, whereas healthy participants and Alzheimer's disease patients did not have category differences. The authors propose that verb representation is grounded in neural networks in which motor brain areas contribute to their processing.

Finally, in the study of Herrera & Cuetos, the authors used a measure of performance that took into account accuracy and reaction times for high and low motion verbs. PD patients were seen on and off Levodopa and presented longer reaction times in response to all pictures when OFF medication. Moreover, regression analysis using RT differences between PD ON/OFF found that higher motor content verbs were more impaired in the OFF state. It is interesting to remark that the use of more fine measures, like RT, allowed the detection of a clear motion effect, not found in the study of Nikumb (2014). Thus, as expected by the multilevel model, in a more restricted situation there will be greater participation of the sensori-motor neural network.

In sum, even with some studies that have obtained opposite results, a deficit in naming verbs was found in patients with PD. Evidences of the multilevel model are obtained by the comparison between reading and naming tasks as well as by the relationship between the semantic attribute of motion of the verb, when very fine analyses are undertaken.

Go/Non Go Task

Using TMS to test the strong view of EC Nguyen et al. (2013) compared PD patients with upper versus lower limb dominance in a go/no go task. Target verbs were 30 limb, 29 lower limb and 30 psych verbs. An interaction was found between PD dominance and upper and lower limb verbs. Patients with greater upper limb deficits were slower in answering to upper limb verbs compared to lower limb ones. However, patients with greater deficits in lower limbs did not show differences in responding to upper and lower limb verbs. These results support Pulvermüller's theory of associative learning, and have refined the studies about PD patients and verb processing concerning the classification of the patients regarding their impairments. Go/no go task does not require deep semantic processing, but it requires a greater amount of attentional resources, and thus the interaction found can be influenced by executive capacities of the patients.

Verbal Fluency

Herrera, Cuetos & Rabiboca (2012) assessed 20 PD patients and 20 control subjects with four verbal fluency tasks: phonological fluency (words beginning in F), semantic fluency (animals and supermarket items) and action fluency (infinitive form of verbs, "things you can do"). Patients were asked to produce as many words as they could from each category in 60s, in ON and OFF Levodopa states. The total of words produced in the phonological and action categories differed between PD OFF/ON and PD OFF/Healthy controls. There were no significant differences between PD patients on medication and controls. An analysis of the frequency of the words produced in action fluency demonstrated that PD OFF emitted words with higher frequency compared to the control group. Results are explained in terms of dopamine dependency for lexical retrieval. The authors mention that patients have difficulties retrieving verbs with greater semantic action content that would be related with an under-activation of motor and premotor areas during the condition OFF medication. The qualitative results are in accordance to the multilevel model in the sense that less frequent or semantically more complex verbs will require motor simulations.

Lexical Decision and Semantic Judgement Tasks

Boulenger et al. (2008) developed a lexical decision task with priming in order to verify the effect of Levodopa. Stimuli were action verbs and concrete nouns. During the OFF state of dopaminergic treatment, no priming was found for action verbs, whereas recovery was found during the ON state. Concrete nouns were not affected by the dopaminergic treatment. These results support the role of motor system in action verbs.

The study of Fernandino et al. (2013a) applied lexical decision with priming (implicit task) and semantic judgment tasks (explicit task) in PD patients and healthy controls, testing the processing of action and abstract verbs in Parkinson's Disease. For the lexical decision task with priming, a set of 80 verbs and 80 phonologically legal pseudo words were used. Half of the verbs referred to voluntary hand/arm actions (e.g., *to grasp*, *to squeeze*), and the others referred to abstract concepts (e.g., *to depend*, *to improve*). The semantic similarity

judgment task used a set of 120 action verbs and a set of 120 abstract verbs (39 action verbs and 36 abstract verbs also appeared in the lexical decision task). The results in lexical decision tasks suggested that controls had faster reaction times for hand-action verbs than for abstract verbs, when in PD patients this effect was not observed. Similar to controls, patients' responses to action trials (2451 ms) were significantly slower than responses to abstract trials (2332 ms). In contrast, patients' accuracy in the action condition (.955) was lower than in the abstract condition (.975). No prime differences were observed. In the Semantic Judgment task, PD had similar results to controls as they had slower responses for verbs than for nouns. In contrast, in this task action verbs responses were slower for abstract verbs. The authors concluded that their results do not agree with general verb impairment among PD, but the differential impairment of the motor network on the two tasks was a "function of a core meanings associated with a word, which supports the amodal approach." Nevertheless, this study shows the impact of the tasks in implicit procedures and seems to favor the processing of action verbs while the explicit processing would give the opposite result, impairment on action verbs. The greater amount of cognitive semantic resources in the explicit task will also favor an interpretation according to the multilevel model.

Imagery Task

Tomasino et al. (2008) applied single pulse transcranial magnetic stimulation (TMS) in the hand motor area of the left hemisphere during three different tasks with action verbs: (1) silent reading; (2) motor imagery, that is, judgement whether the written verb involved hand rotation; and (3) judgment of frequency of occurrence in a newspaper. TMS did not alter the time of responses of silent reading and of frequency judgment whereas in rotation imagery task, responses were more rapid (compared to TMS vertex). The authors clearly postulate that their results do not support the strong EC view. Motor hand area is not mandatory for comprehension of verbs *per se*. Although the EC theory postulates that in order to understand a verb there is a simulation of an action, they only found motor area involvement in processing verbs when the task explicitly requires simulation of the action. Once more it is shown that the grounded representation of verbs depends on the type of task and the complexity of semantic resources required.

Generation Tasks

In these tasks participants are given a word and are required to generate a semantically related item in the same or in a different morphological category. Two intra-category tasks - noun-to-noun (NN) and verb-to-verb (VV) and two inter-category tasks - noun-to-verb (NV) and verb-to-noun (VN) are usually employed. This task is cognitively demanding because the subject must engage in lexical search and requires deep semantic processing to compare the probes with the responses to be given. Six studies used this task, and two of them associated the task to fMRI. In all five studies PD patients had a disproportionate deficit in verb generation compared to nouns. However, three studies (Peran et al., 2003; Castner et al.; 2008 and Crescentini et al.; 2008) explained the deficits in terms of the amodal model of semantic processing and attributed differences to lexical selection problem. Castner et al. (2008) tested

patients in STN stimulation condition (ON vs OFF state) and demonstrated that semantic attributes (visual and motor features) did not impact performance. The two fMRI studies (Perán et al., 2009; 2013) showed more activation of the left prefrontal cortex in verb generation. This area was also activated in manual simulation of the same actions, supporting EC theory. In this task the multilevel model predicted this activation and therefore we can conclude that these type of assessments can be useful to test the assumptions of EC in PD. Finally, Herrera e Cuetos (2013) invited patients and the control group to generate semantic related words based on 10 verbs (to sleep, to ask for, to stop, to cry, to cut, to touch, to climb, to jump, to run, to swim) and 10 nouns (flight, traffic light, mill, anchor, bus, cup, key, flute, umbrella, pen). Authors measured the strength of semantic association between response and stimuli, comparing with normative database responses in the healthy adult population. PD patients off medication said verbs less associated with the target compared with when they were on state. IN OFF state patients generated less semantic related responses for verbs than control groups, while PD ON have the same performance than controls.

Semantic Similarity Judgment Task

Kemmerer et al. (2013) exposed healthy controls (NC – normal control group) and PD patients in ON and OFF state in semantic similarity judgment task (SSJT) using three verbs in a triangular array — one at the top and two at the bottom — and the task was to indicate, as quickly and accurately as possible, which of the two bottom verbs are more similar in meaning to the one on top. For example: “*trudge limp stroll*”. Triangular array was presented in 5s followed by 1s of blank screen. PD patients failed to respond to significantly more items in OFF condition than in ON. There was no effect of group, indicating that PD patients did not perform significantly worse than healthy participants. Authors did not find accuracy differences between PD ON and OFF. Relative to RT, Kemmerer et al. (2013) observed that the RTs for change of state were longer than psych verbs in PD ON < NC and PD OFF < NC. RT of action verbs and no-action verbs did not differ between groups.

Lexical/Semantic Processing of Phrases

Fernandino et al. (2013b) investigated PD patients and healthy control subjects in a task of sentence plausibility judgements. Participants had to decide whether the sentence was plausible and to respond as fast and as accurately as possible by pressing one of the two response buttons with their preferred hand (all participants chose to use their right hand). Fifty nonsense sentences and 100 plausible sentences were presented. Nonsense sentences were grammatically well-formed but constructed so that the verb was semantically incompatible with one or both of its arguments (e.g., “*The business is pinching the sunset*”). The plausible sentences were divided into four conditions: literal action (“*The woman is pinching my cheeks*”), non-idiomatic metaphoric action (“*The cost is pinching the consumers*”), idiomatic action (“*The business is pinching pennies*”), and abstract (“*The business is saving cash*”). The 25 sentences in each of the three action-related conditions were built by combining a set of 21 action verbs – all referring to hand/arm actions – with different noun phrases. Patients, but not controls, were slower to respond to literal and idiomatic

actions than to abstract sentences. Groups did not differ in accuracy levels but in reaction times. The authors interpreted their findings in terms of the stronger version of EC. However, a gradation of activation of motor areas is proposed, according to semantic properties of the verb in the context of a sentence. This gradation and the differences in time, but not in accuracy, could also be explained in terms of the multilevel model.

Action Compatibility Effect

Ibáñez et al. (2013) evaluated PD patients and healthy control participants. Authors used the Action Compatibility Effect paradigm. Participants listened to sentences that implied an action with the hand in a particular shape as well as neutral sentences that did not imply an action with the hand. Participants indicated as quickly as possible when they understood each sentence by pressing a button using a pre-assigned hand-shape. No differences between compatible and incompatible trials were observed in PD; that is, differently from controls there was no ACE effect in the patients showing less participation of motor circuits. These results can also be explained by the EC account.

CONCLUSION

Controversies persist in this area with some researchers favoring the strong version of the EC theory, stating that integrity of the motor system is necessary to process action verbs even when used with figurative meaning whilst others support a weaker version of embodied cognition, that is, motor representations may enrich the semantics of verbs but are not necessary for the comprehension/production of verbs). However, the present review points out that controversial results may reflect the variety of objectives and experimental paradigms, which may influence the results and interpretations. Therefore, based on the multilevel theory, it is easier to understand the task effects. The clear cut between the amodal view and the strong EC account can be explained in terms of contextual cues and task cognitive demands. In summary, it seems possible to conclude that more automatic language use situations, such as spontaneous conversation, would not evidence the participation of the motor system in semantic processing. On the other hand, the embodied components are more consistent when the task requires deep semantic processing and more attentional and executive resources.

The studies that aimed at verifying the impact of pharmacological treatment and DBS have shown positive effects in PD. It is not clear though, whether the effects in semantic processing are due to better attentional and executive functioning or to specific effects on the motor system. Some studies point to the relationship between the type of motor impairment and lexical semantic processing; however we still don't have evidence of the several subtypes of PD. For future studies, we emphasize the need for identifying relevant semantic attributes and analyzing their impact in tasks requiring different levels of semantic processing. Few studies considered semantic attributes, and even fewer compared the same group of patients in different tasks. Therefore, the diversity of experimental approaches and tasks require the continuity of researches in this area to understand the effects of PD in language and treatment alternatives.

ABSTRACT

This chapter aims to acquaint the reader with the current debate on the prevalence of oral and written linguistic difficulties as a precursor of Specific Learning Difficulties (SLD). The barrier created by scientific literature in terms of the diversity of terminology regarding the definition of these pathologies – which clearly reflects the interests of various fields – has given rise to multiple nosological classifications to define the same disorder, which has in turn hampered a diagnostic classification. This situation, in addition to a historical constant of disagreement regarding the definition and identification of SLD, has led to the identification of SLD in a child who has shown no signs of intellectual, sensory, physical or perceptive impairment in their learning that would keep them from reaching the objectives for the course or corresponding academic year in which they are enrolled.

Some factors that influence the appearance of SLD are *Speech Delays* (SD) and/or *Oral Language Delay* (OLD), as well as *Written Language Delay* (WLD), especially reading difficulties, as shown in epidemiological studies indicating a high prevalence. Likewise, delays in different linguistic components (semantic and/or syntactic) also significantly affect the comprehension and assimilation of text content, leading to learning difficulties. Therefore, we understand the need for a more comprehensive study of the relationship between delayed linguistic components and reading comprehension

and fluency, given the high rates of prevalence during the first years of school and the possible origin of academic disabilities among students with LD.

In this respect, knowledge of the prevalence of linguistic difficulties during early childhood can facilitate the early detection and prevention of LD in the student population. This is due to the fact that the majority of language and communication problems will appear in the classroom environment, which incorporates the demands and implications of the teaching and learning process.

A recent study (García-Mateos, Mayor, De Santiago y Zubiáuz, 2014) on the prevalence of language, speaking, voice and communication pathologies observed that, among the epidemiological profile of different pathologies present until adolescence, WLLD, OLD and SD constitute the greatest percentage as compared to other linguistic pathologies, and that gender differences were also present.

From this perspective, teachers are considered the most critical and responsible factor in the educational changes and improvements for the child. Nevertheless, teachers perceive certain limitations in their ability to intervene with these students within the classroom. We would therefore like to provide teachers with key epidemiological tools using the “*Precede-Proceed Model*” as an early detection and prevention device for Specific Learning Difficulties (SLD).

INTRODUCTION

1. Learning Difficulties. Historical Perspective, Updating and Clarifying Concepts

The study of Specific Learning Difficulties (SLD) has attracted great interest in education, due to its high prevalence and to the difficulty in defining and agreeing on its definition, explanation, detection and intervention. Its definition and the difficulties that are included within it have changed over the years, depending on various stages that have been marked or influenced by the context or the socio-political-educational framework that has surrounded them at all times. In the study of SLD there has been a change in trend, from medical understandings, to other more educational approaches, which has generated different theoretical models to explain the SLD from different paradigms giving different explanations to such disorders [1]. SLD constitutes a controversial category because of the lack of a broad consensus in defining or naming them, receiving nosologies as Diverse Learning Disabilities (NJCLD, 1998), Specific Learning Disabilities (IDEA, 1997), Learning Disorders (APA, 1995), Learning Disabilities (Craig, 2001), Learning Disabilities (Smith, 2003) or last name provided in the DSM V TM as a Specific Learning Disorder (APA, 2013) [2]. This diversity of approaches and designations means that there is no a unanimous agreement on the definition and explanation thereof.

Over time, the improvement of social conditions and general knowledge about the problems and improvement of diagnostic tests have managed to consolidate the area of Learning Disabilities as a specific discipline. This has been helped, too, by the consensus established in recent times in the international scientific field, professionals in the subject and expert associations in educational contexts around the American conceptual definition of learning disabilities proposed by the *National Joint Committee on Learning Disabilities* (NJCLD, 1998). In response to this proposal “*Specific Learning Disabilities is a general term that refers to a heterogeneous group of disorders that manifest themselves in difficulties in*

the acquisition and use of skills of listening, speaking, reading, writing, reasoning or mathematical abilities. These alterations are intrinsic to individuals and can take place throughout the life cycle. Problems in self-regulation conducts, social perception and social interaction can coexist with the LD, but do not constitute in themselves a LD. Although Specific Learning Disabilities can coexist with other handicaps (eg, sensory impairments, mental retardation, emotional disturbance) or with extrinsic influences (such as cultural differences, insufficient or inappropriate instruction), they are not the result of those conditions or influences" [3] (NJCLD, 1998, p.65).

This definition, which is established through five foci or criteria (Table 1), has among its objectives the differentiation of SLD from other conditions that may affect poor school performance, eliminating thus the possibility that any school problem be classified as learning difficulty and distinguish it from what it would be the difficulty or inability to learn or *Learning Disabilities*. Reference is made to certain specific problems related to learning skills in the field of oral or written language, calculation, motor and perceptual aspects, etc... It is noted that the SLD appear throughout the life cycle, ie, they are not only related with the infant stage but are conceptualized more as an intrinsic factor which causes poor academic performance [4, 5]. In this definition, and from a primarily educational focus, the essence of what we understand by SLD is included with the aim of making decisions of service provisions in the educational field [6, 7].

Table 1. Five Components of Specific Learning Difficulties

Criteria Conceptual Definitions of the SLD (NJCLD-1998)
i. Heterogeneity
ii. Significant difficulties in the acquisition and use of understanding, speaking, reading, writing, and math reasoning skills.
iii. Intrinsic character
iv. Assumption throughout the life cycle
v. Conjunction with other disorders or with extrinsic influences.

Despite the consensus already provided by this definition (NJCLD, 1994), it is also true that it can not be operationalized and empirically validated. Therefore, and with intent to fill these gaps, new attempts have emerged in recent years in order to come up with an operational definition. In this sense, Santiuste and González-Pérez (2005, p.119) make the following definition: *"Learning disabilities are constituted by a heterogeneous set of problems whose origin is probably a dysfunction of the central nervous system. They manifest themselves primarily with problems in the linguistic field and processing defects in major cognitive factors (attention, perception, memory) and, derivatively, in the area of the main instrumental disciplines (reading, writing, mathematics) and, secondarily, in various areas of the curriculum (experimental sciences, social sciences, second language). They are also associated with personality disorders, self-concept and sociability and these can occur throughout the life cycle of the subject" [8]*

From this operational definition these authors establish a set of basic features attributable to children with LD:

- a) Intellectual capacity within the normal range according to standardized tests.
- b) Inadequate academic performance presenting deficiencies in basic instrumental areas (reading, numeracy, writing, and language).
- c) Alterations in cognitive processes (perception, attention, memory) and problem solving.
- d) Chance of developing psycho or socio-environmental problems that interfere with the success in learning.
- e) The cause is primarily focused on the Central Nervous System (CNS) such as emotional disturbance, dysfunction or injury.
- f) It isn't the result of intellectual disability, sensory deprivation, serious emotional severe emotional disturbance or cultural and instructional factors.

Operationally, the approach also provided by the National Joint Committee (NJCLD, 1998) [3], materializes in the diagnostic criteria gathered in two major international diagnostic systems: ICD-10 International Statistical Classification of Diseases and Health Problems (WHO; 2001) and DSM-V (APA, 2013) [9]. The first classification system establishes as specific school learning disorders the ones referred particularly to reading skills (F81.0) specific spelling disorder (F81.1), specific calculation disorder (F81.2), mixed developmental learning school disorders (F.81.3), other developmental disorders related to school learning (F81.8) and disabilities in the development of unspecified school learning disorder (F81.9). Meanwhile the DSM-V (APA, 2013) changes the name of learning disability (LD) by specific learning disorder (SLD) which includes the reading difficulties disorder (reading impairment), writing difficulties disorders (written expression impairment) and Mathematics difficulties disorder (with impairment in mathematics) [5, 10]. The latter classification, as in the *Public Law 108-446, the Individuals with Disabilities Education Improvement Act* (IDEA, 2004) also proposes to eliminate as identification criteria the discrepancy between intellectual ability and academic performance.

In the international context, the SLD have been established in models based on the discrepancy between IQ and performance of students in such a way that the identification of the student with SLD was performed when he/she showed learning alterations learning in their academic performance with regard to their learning potential (DSM-IV, 2002). This criterion, called into question today, led to the concept of LSD as a synonym of the existent discrepancies between academic achievement and intelligence [4].

The application of these rules and the consistent, historical disagreement on the definition and identification of SLD led to a high percentage of children being placed in special education classrooms when they could have received instruction within the regular classroom. This fact prompted students to be identified with SLD, ie, false-negative, and though they didn't present difficulties in the intellectual, sensory, physical or perceptual level, they do have gaps or errors in their learning. In this way, they are prevented from achieving the objectives of their current academic year [11]. This has led to the prevalence rates to become high. For example, in the report issued by the US Department of Education during the academic year 2000-2001, more than 48% of a population of 5.7 million children and adolescents were classified with LSD. Similarly, in the study conducted in Spain by the aforementioned authors, 56% of a population of 5738 students from 1st to 4th of ESO (Obligatory Secondary Education) showed to have SLD according to the teacher criteria in not achieving the course objectives or cycle. These data show that the SLD category is being

used by educational institutions as a nonspecific category which causes many children to fail in the school system [11].

For instance, since the beginning of the research on learning disabilities in reading and under the paradigm of discrepancy criterion, it was assumed that delayed readers with high IQ (dyslexic) would be part of a different group of delayed readers with low IQ, because they show a different profile related to cognitive and neurological aspects. However, up to day there is no empirical evidence that truly there exists, neurological, cognitive and aetiological differences between dyslexic and reading disabilities, as demonstrated by studies in the context of the Spanish investigation in recent years. In the field of cognitive processes involved in reading (ie, speech perception, phonological awareness, speed, naming, verbal working memory, orthographic processing and syntactic processing) it has been shown that differences of lexical access between normoletores and dyslexics are not interfered with the influence of intelligence, ie a low IQ score does not necessarily predict low reading achievement [12]. Likewise, students identified with SLD in reading do not seem to benefit more from instruction in phonological processes than those showing no discrepancy in IQ-reading performance [13]. That is, the same is evidenced in the field of arithmetic in which it is found that the cognitive profile of students with and without IQ-performance discrepancy is very similar. The interaction between IQ and reading achievement appears to be interfered with transparency-opacity of the spelling system of the language in which the child learns to read. For example, the study in English-speaking Canadian children found that students with low IQ Verbal (<80) was associated with poor performance in reading and spelling. This association was not found in Spanish children [14]. The authors concluded that the interaction between IQ and low reading performance could be more significant in opaque orthography (ie, English) rather than in orthography (ie, Spanish).

From an evolutionary perspective, Jimenez, Rodriguez, Guzman and Garcia indicate that difficulties in cognitive processes in students with reading difficulties become worse as the academic level requires greater reading skills, maintaining these differences with normoletores [15].

Therefore, from these operational approaches related to the analysis and development of the cognitive processes involved in learning, we understand that the SLD can be detected and identified from the reading, writing and arithmetic skills. We must not forget the important role of oral language proficiency in the development of these capabilities, ie the development of speech and language. From the context of the teaching-learning identification, some criteria are needed in order to help us determine the cognitive and linguistic profile of students so as to provide an appropriate intervention if necessary.

From this area, the start of a child schooling period may increase the language requirements for socialization and learning. During the Kindergarten Stage -3 to 6 year's of age-, their linguistic competence extends and strengthens beyond the familiar patterns. In fact, the school environment becomes for a given number of children, the context where is most clearly evident the linguistic difficulties in their different levels of severity. These preschool years are critical for the consolidation of oral language proficiency and it is at this time, when teachers more easily observe significant differences regarding their oral language proficiency. This circumstance allows the first comparison of students, verifying that in most cases students proceed normally while others only get it with certain difficulties or therapeutic support. These early school years are crucial for language development test and for observing who can operate for themselves-natural course-, or who will need a more professional support

so as to complete this educational cycle with proper oral competence to accomplish other learnings.

The role of teachers, therefore, will be the key to an early detection of the different language pathologies because, in most cases, it is the teacher who first detects these and seeks assistance from the specialist when children need support to cope with the pace of the class. However, teachers perceive themselves with important knowledge gaps regarding the effective detection of language disorders. In the field of SENL (Specific Educational Needs Language) teachers request more training and practical experience, as well as specialized advice for the detection, assessment and intervention of children with SENL [16]. In this sense, the previous investigations found that the training guidelines of secondary school teachers regarding the intervention in the delays of oral and written language inside the classroom, improves effectively those skills related to writing and reading comprehension of students with lower language proficiency [17]. Therefore, we believe that the educational system should be able to adapt to the needs of the child within the classroom setting, adjusting the pace and school demands to each student with problems.

2. Acquisition of Oral and Written Language Learning and Its Difficulties with Relationship

The relationship between *Speech and Language Delays*, as part of the same continuum with *Written Language Learning Difficulties* (WLLD) has been demonstrated by numerous studies [18, 19, 20, 21, 22] and its impact on *Specific Learning Difficulties* (LSD) [23, 24] and emotional and / or behavioral problems [25, 26, 27]. In the acquisition of written language the child must learn the grapheme-phoneme correspondence to transform the letters into sounds (reading) and sounds in words (writing). Until about 4/6 years of age, children are not aware to identify the phonological structure of spoken words that will allow them later to turn them into written words. Thus, any mistake in phonological auditory discrimination will hamper the identification and order of phonemes in word structure, thus hindering access to their meaning. This meaningless and slower recognition of words makes it difficult to assimilate these words and their meanings, producing a smaller lexical repertoire and less reading practice which requires more effort, thus, causing children to become less effective and demotivated readers due to the delays in their phonological system [28,29,30,31]. We must consider that language difficulties, being these oral and written, are present throughout the school years [32, 33] and can continue affecting decoding words and reading fluency still in the final stages of Compulsory Education [34, 35, 36, 37, 38] favoring learning difficulties and / or behavior problems in the classroom [39, 40, 22, 41]. Therefore it is found that the problems in phonological decoding directly affect both the learning of writing (natural spelling) as well as reading fluency [42].

Subsequently, from the first years of primary education, and once the phase of "*learning to read*" has been overcome, the child should be able to "*read to learn*". The reading performance which enables learning can be observed in terms of understanding and assimilation of the text, verifying that it is the semantic-syntactic language development, both comprehensive and expressive, the factors that greatest influence on this process. From this approach we could highlight that reading comprehension can be predicted from the expressive and comprehensive language competence in relation to semantic lexicon and morphosyntactic

acquisition [16, 41, 30], the same applies to writing [43]. In this sense, the previous study shows that language delays affect reading comprehension primarily during the primary stage. It is observed that reading comprehension is directly affected by the lack of vocabulary (comprehensive semantic language delay), but this does not happen when it affects the comprehensive syntax. This could be explained by the superficial understanding of the text generated from the content-rich "keywords" [44, 45, 54]. This type of learning would require the constant help of the teacher, who adapts the syntax in order to assimilate and integrate the ideas in the text. Similarly problems were recorded in written expression when the expressive language delays are of syntactic nature. Finally, the mixture of-semantic / syntactic difficulties of comprehensive and expressive nature hindered reading comprehension as well. We can conclude, then, that inadequate written language proficiency greatly influences the acquisition of curriculum learning, since the slow and costly exercise of reading and writing originates in turn, poor motivation towards learning from these written texts because assimilation needs reflection and abstract ideas contained therein. Therefore, learning from the written text still requires even greater efforts that will most likely increase the occurrence of the SLD [46, 47]. We believe that it is necessary to acknowledge the diversity of linguistic pathologies in the written language as well as the SLD, given this relationship between the oral language delays and the school stage at which they become visible. To know and identify oral pathologies in time, will allow detecting potential learners with SLD before starting written language learning, thus, adopting prevention measurements of WLLD and SLD.

3. Prevalence Studies on Linguistic Difficulties at the Beginning of Schooling Years

In order to accurately adjust the data related to the population at risk with linguistic pathologies, we believe that the epidemiological prevalence studies are those which most precisely describe this diversity [48].

This type of descriptive studies and their results allow the so-called "*Generator Hypothesis Cycle*" [49] and will enable, from the obtained data, to pose new hypotheses and new experimental studies. This research cycle requires three basic steps: 1) Identify, define and describe the problem; 2) establish by prevalence studies associations among the different variables which have been analyzed with statistical values; 3) establish criteria for causality with the elaboration of new experimental studies or clinical trial.

In the field of epidemiological studies framed in the SLD we have three main research areas: the prevalence of Delays, Speech and Language, the influence of different Special Educational Needs (SEN) and finally the relationship between Difficulties in Written Language Learning (DWLL) and appearance of the SLD.

Regarding the prevalence of oral communication difficulties, the review of Law, Boyle, Harris, Harkness and Nyle investigation shows that most prevalence studies have focused on Speech and Language Delays of Specific nature and these only address children aged between 3 and 11 years old. Most of these investigations were also carried out from medical-phoniatric areas [50].

Overall, the results show that about 5.95% of children suffer from some type of oral language disabilities. However, these figures could be higher if we include those derived from

other more serious diseases such as cognitive, auditory, motor and / or neurological deficits, which may double their percentages of occurrence [51, 52, 33] .

Another important factor in these types of studies is the exclusion of Learning Difficulties in the Written Language as a diagnostic category itself. The recent studies shows that the epidemiological profile of the different language pathology throughout the life cycle are WLLD (19.1 out of the sample) which exceed a high percentage of the rest of oral language pathologies.

These WLLD children are between 6 and 10 years of age (60% of WLLD cases) and between 11 and 15 years of age (33.9% of these same cases). Likewise, a high percentage of Phonological delays (14.2% of the sample) and Primary Language Delays (8.1% of the sample) are found in the epidemiological profile compared to other language pathologies [33, 53].

Regarding age, it is observed that the largest number of medical consultations stands up to 15 years of age, decreasing significantly after adolescence. These data confirm previous researches that also have the highest prevalence rates from early childhood through adolescence. These results confirm previous researches which show that the demand for care is also located preferably up to the end of adolescence [51, 55, 56, 57, 58].

Moreover, there is very little research on prevalence of the SLD, which analyzes their presence in the classroom and that can be compared with the presence of other communicative disorders [59]. However, we note that one of the major setbacks in such investigations is related to the differences in the definition and diagnostic classification of the different language pathologies and of the SLD.

In this chapter we wish to emphasize the high prevalence of language difficulties which are present during the early school years because the data provided by the International Dyslexia Association (2002) show that 15 to 20% of the school population has a learning difficulty based on language. This circumstance, as will be dealt with later from prevalence data, becomes one of the precursor's factors to be considered for the identification and diagnosis of SLDs.

In relation to the school population research results show that a high percentage of children with SEN have some type of LD. According to the DSM-IV-TR (2002) between 2-10% of all school-age children have some LD derived from different SEN. However, other studies show different percentages. This discrepancy may be due to differences in classification and diagnosis of various LD. In this regard, recorded data between 5-10% [60], between 16-20% [61] or between 10-15% [62]. Finally, the data provided by the US Department of Education (2002) raises the amount up to 48% of the school population. In this sense, the broadest longitudinal study carried out regarding the association between the LSD and Language Delays in the same students from Primary to Secondary school level show that the order of prevalence of SEN is located in the following ranges of prevalence: 17.93% LSD in Primary and then 19.10% in Secondary; a 13.4% of Language Difficulties is found in Primary and a 12.40% of cases in Secondary again. As noted, Learning Disabilities increase in proportion as students advance in schooling. The same is reflected in the classification and diagnosis of SLD by the DSM-IV-TR (2002) indicating that, within their different categories, the WLLD are the most common learning disorder within the school population [59].

Accordingly, the recent work [63] shows that 21.4% of the school population has one or more SLD being the WLLD those with higher prevalence (12.3%) opposite to the mathematical difficulties, with (3.0%) or the combination of both (6.0%). Likewise, the study

also shows that the SLD are more common in girls than in boys (3.5%), and which in turn the girls showed more SLD more related to language proficiency unlike boys whose prevalence of SLD was more related to difficulties in mathematics. However, we should consider the fact whether these difficulties in mathematics are due to problems in the calculation or to mathematical reasoning where language skills are essential [64]. Another important finding is that the group of younger school students shows one or more specific learning difficulties.

Finally, the study of the prevalence of the SLD associated with WLLD shows some factors that must be taken into account. One of the most important, already referred to above, is the question of transparency or opacity of language phoneme-grapheme correspondence being the English language the one which gets highest recorded prevalence in reading difficulties. Within the SLD, most studies agree in noting that problems in written language have the highest prevalence among this type of language difficulties. We can find percentages ranging from 80% [65, 66] and 5-17.5% [67] of the school population studied.

The most detailed study recorded that 16.9% of secondary students have some type of SLD, which has been generated due to difficulties in learning written language, and of these, 3.2% are due to problems with reading and 7, 6% with writing. Regarding reading difficulties they observed that 32.5% are Surface Dyslexia, 21.2% Phonological difficulties and 10% Mixed. Likewise, with regard to problems in acquiring writing, it is noted that 52.7% of students have difficulty with spelling rules, 18.1% with natural spelling grapheme / phoneme -Conversion and 29, 2% in both [11].

Finally, the fact that the dreaded academic failure starts in the first years of primary - although the final dropout occurs during the stage of the Secondary stage in the forms of-failing, grade repetition, absenteeism... [68] leads us to propose that the early detection of oral and written language difficulties can be a major factor and that its early intervention becomes one of the initial steps for the prevention and treatment of SLDs.

Therefore, an appropriate, specialized care is needed inside the classroom setting. Having specialist teachers who can intervene and advise the rest of teachers will be the key that will lead to the decrease of the high proportion of children with some form of SLD. Specific care services are needed, not only from the health sector, but also within the school context, thus enabling teachers the possibility of planning the number and types of pathologies that appear more frequently in classrooms. In the case of the SLD, identifying children at-risk before their learning process is hampered, is an essential task to be carried out by the teachers themselves.

4. Action Guidelines for Teachers: Model for Preventive Application

Different studies agree in identifying risk factors that predispose SLD and that can be grouped into: personal variables (family history of dyslexia, language delays, metalinguage skills and / or basic cognitive processes), contextual variables (family sociocultural familiar or school environment) or the combination of both [69]. Of all these, language delays of phonetic-phonological nature would affect the learning of reading [70, 71] and the delays of lexical-semantic and grammatical nature would do so on the understanding and learning at text level [72, 73]. Similarly, inadequate development of metalinguistic skills especially phonological- awareness [31, 74] along with deficits problems in verbal -memory basic cognitive processes, selective attention and perception - [75, 76] do have a direct impact on the appearance of WLLD and derived from these, also on the SLDs.

Given the above, we can wonder what would be the best intervention strategies to prevent the SLD from the linguistic competences. Kaderavek & Sulzby (2000) recommend training in phonological decoding and vocabulary extension [77]. They also advise the training in discursive skills as a key competence for reading comprehension and writing. The previous investigations suggest that the practice of inferences and anticipations regarding the contents of the text becomes one of the most remarkable preventive factors for assimilation and learning [78]. We believe that this will be one of the main keys in the prevention and correction in SLD.

Thus, we could raise the idea that if we set the delays in speech and writing, as diagnostic criteria for possible SLD, many children would benefit from early attention established on preventive strategies instead of re-educative ones when these difficulties appear: "Prevent before than cure ". This idea was raised at the *Precede-Proceed* linguistic model from epidemiological studies as a guideline for intervention and language pathology detection. We believe that, in the case of the SLD can be also applicable [48].

As a model of intervention, and according to new operational definitions of SLD the response to intervention (response-to-intervention) is postulated. This criterion arises in 2004 from the review of legislative regulations in the United States Act IDEA The Individuals with Disabilities Education Act. The main novelty that it provides for the procedures in the identification of SLD is the replacing of the *discrepancy* criterion (the use of CI is not required for the identification of students with SLD) by the response to intervention. *Heterogeneity* criteria are maintained including eight domains (oral expression, listening comprehension, written expression, basic reading skills, fluent reading, mathematical calculation and mathematical problem solving), as well as grounds for exclusion, though at present, it is carried out with more complex procedures in which evidence that the student has received specific instruction regarding the specific academic area is requested. It is also required a continuous monitoring at different intervals of time on the response of the prospective student with SLD and the instruction followed, thus emphasizing the important role of education in the prevention and identification of SLD [4, 10]. This refers to an early assessment on the response of a pupil who presents sufficient indicators of obstacles for his/her future learning. In this way, a personalized intervention program based on scientific research can be planned, which matches their individual needs in order to make educational decisions depending on the evolution of their learning. It is all about an adequate assessment of the student's response to that instruction and intervention.

Nowadays, it is common to talk about three levels of intensity and six steps in the procedure for considering intervention [79, 10, 80]:

- ✓ *Level one* (preventive intervention). Implementation of quality education programs in what refers to general education for the whole class. This requires continuous assessment with brief tests in order to identify underperforming students or those at risk of developing a SLD. To carry out a follow up for 1 or 2 months on their responses to the use of these general education programs.
- ✓ *The level two* (intervention). It should be used as soon as possible and includes reinforcement in small groups (1-5 children), offered by a specialist tutor or a special education teacher. At this level programs and strategies are designed to improve teaching *level one* offered to all students. The intervention at this level will last approximately 9-12 weeks with a continuous assessment. The end of this phase can

lead to three decisions: (a) the student returns to the general class, (b) the student receives a second application program on *level two*, (c) those students who have not improved at this level, may go to *level three*.

- ✓ *The level three* (specific education). At this level the SLD is diagnosed and intervention is offered. The intervention, which may occur individually or in small groups is tailored to the student's needs and involves continuous evaluation. As improvements start taking place and the student reaches the expected grade level, he/she must be taken back to the *level one* and if he fails again in the mainstream class he/she can return to *level two or three*. We can proceed in this way until the student can stay at *level one*. Only if the student does not respond positively to interventions in series will the risk of having SLD be estimated and then the use of special education services evaluated.

Therefore, from the perspective of a model of response to intervention, well-founded intervention programs are proposed, which may be applied intensively on those schools where it is suspected that there may be a future SLD [81, 10]

Therefore, the main rationale underlying the model *response to intervention* is *prevention*, so that, many children without disabilities or serious disorders who participate in these programs (inside or outside the regular classroom), are no longer intervened dramatically and are incorporated into the normal course routine with their age mates. Otherwise, without preventive intervention, students could join the ranks of those who fail in school, not because of a SLD, but because their special personal conditions or school biography.

In short, the evaluation is oriented towards the student's response so that make decisions about interventions can be made, which will be marked by the evolution of the learning process. A clear distinction is made between poor performance, due to inadequate teaching process, and low performing related to the individual profile. Poor performance will be considered relevant, only if there is evidence that the student has received adequate instruction and yet an increase in their level of academic performance is not observed [4, 15, 82].

Chapter 3

LANGUAGE DEVELOPMENT AS A MARKER OF NORMAL BRAIN DEVELOPMENT

ABSTRACT

Depending on how broadly or narrowly defined, language can include multiple processes which go well beyond speech production and comprehension. Though typical language development is a stepping stone process based on its component parts, such as phonology, morphology, syntax, and pragmatics, it quickly branches into a vehicle for broad communication, including gestures, social and affective orientation toward others, and the facilitation of our learning and thinking skills. Considering its involvement in so much of what we do, language has been proven to be an extremely complex and diffusely distributed function in the human brain. Considerable research shows that individual language process development proceeds in a very predictable manner and parallels specific areas of brain development. Research appears to support a critical period hypothesis during which the brain is maximally sensitive to specific types of language stimulation required for acquisition of skills associated with the next developmental phase. Thus, it seems clear that both genetics and environmental factors are important. Delays in the development of language skills and acquired deviations from normal language functioning can often be diagnostic of a pathological process. Given the great specificity in knowledge regarding the many neuroanatomical structures involved in language, language symptoms can be reasonably well localized in the brain. When language development deviates from the normal timeline, clinical interventions are often essential. Most evidence suggests that earlier intervention is more efficient. There are many creative and evidenced based treatments for language delays; however, depending

[#] Families Forward, Martinez, GA.

on the severity and duration of the delay, the amount of treatment needed and the prognosis can vary widely. In cases where a delay is extreme there are often other noted cognitive and social deficits. Some speculate that delayed language could even plausibly limit the development of many other cognitive skills. This chapter discusses the more current broad conceptualization of language development and many of the evidence-based treatments. These include behavioral interventions such as Discrete Trial Training, as well as other methods: parent mediated, narrative mediated, social communication interventions, and sensory based interventions.

Language ability is not only universal, but of vast potential, and related to numerous other cognitive and social functions. Although we often tend to think about language primarily as a tool we utilize to communicate with others, it is a far more complex construct that frames our entire human experience, both external and internal. Our sensory input, affective states, and our thoughts are coded in language, so we can process, interpret, and/or store information for future use. As such, language becomes a necessary mediator of our interactions with the self and our environment; it furthers other cognitive abilities and allows us to learn, develop, and adapt to our circumstances. Consequently, depending on how broadly or narrowly defined, language includes multiple processes that go beyond speech and its comprehension. For example, language can subsume communicative gestures (Goldin-Meadow et. al., 2014) and social and affective orientation toward others (Locke, 1997). Thus, we can recognize four broader domains of language processes: perception, reception, production, and behavior; each with its own set of complex mechanisms being subserved and facilitated by corresponding neural circuitry and neuroanatomical structures.

Recent research have extensively broadened our knowledge of the neurobiological basis of language. The localizationist theories contrived to identifying discrete brain structures, with Broca's and Wernicke's areas seen as responsible for most of our language functioning, have been challenged (Lieberman, 2002). Current conceptualizations provide a comprehensive understanding of the complexity of the neuroanatomical support required for various language processes. Moreover, we appreciate that many of the brain structures involved in language functions are interconnected (e.g., the superior temporal lobe connected with the arcuate fasciculus to the inferior frontal areas) and thus interdependent (Pulvermüller & Fadiga, 2010).

Similarly, we are beginning to understand that the courses of language and brain development display equally intertwined experience-dependent relationships. For instance, we commonly accept that certain language functions need to be acquired during a sensitive or critical developmental period (Locke, 1997). Although a dearth of required stimulation can prolong these windows of opportunity, the absence of it can lead to both functional impairment and abnormal neural circuitry and organization (Knudsen, 2004). Thus, a child who has not acquired a sufficiently robust lexicon prior to the activation of their analytic mechanism, which is supported primarily by left hemisphere structures, can experience word learning delays and increased hemispheric symmetry (Locke, 1997). Additionally, while linguistic behaviors are subserved by intricate neural processes, language acquisition itself is a manifestation of brain development occurring to accommodate the expanding repertoire and complexity of those behaviors (Sakai, 2005).

Interdependent relationships can also be observed between language skills and cognitive abilities. Even very early language processes like orientation to human voice, learning utterances, and acquiring a lexicon (Locke, 1997) require the use of attention and short term memory. In turn, acquisition of language skills facilitates the mastery of more advanced cognitive tasks (Goldin-Meadow, 2014) and predicts future academic achievement (Qian, 2002). For example, Qian (2002) found that level of lexical competence predicted performance on reading comprehension assessments. Moreover, language serves as a representational resource necessary for understanding of abstract concepts and development of the theory of mind skills (Clark, 2004). In essence, language development is dependent on specific cognitive abilities, but language is also the code we use to build many other cognitive skills.

Having a better grasp of the intimate connections between language, brain, and cognitive development can have far reaching applications in clinical practice. Language abilities and their precursors are readily observable early in the human development. Thus, very early on, deviations from the typical developmental course of language acquisition can be treated as potential indicators of neurolinguistic issues and brain dysfunction. Timely attention to an atypical language behavior and development can lead to a more immediate discovery of potentially problematic neuroanatomical irregularities. In addition, early interventions can maximize language ability potential as well as school achievement. For example, providers can focus on ensuring a sufficient level of appropriate linguistic stimulation during the critical developmental periods. Even for those children whose language functioning has already been affected by lexical delays or more severe impairments (e.g., Specific Language Impairment disorder; SLI), appreciation of the possible etiology of the dysfunction as well as its implications for neurological processes and academic performance may facilitate selection of more appropriate, comprehensive, and effective treatments.

NEUROANATOMICAL STRUCTURES ASSOCIATED WITH LANGUAGE

Our current understanding of functional anatomy of language is highly developed and has diverse roots, including the scholarly works of many linguists and neuroscientists. Empirical data from a variety of sources, such as the study of individual cases of developmental or acquired language dysfunction, clinical pathology, and brain imaging, supply evidence of the phases of language development and their origins in neuroanatomical structures and processes. A full description of the intricate neuroanatomy of language is far beyond the scope of this chapter. However most basically, clinicians often simply dichotomize language by discussing the anterior language area, involving Broca's area, and the oromotor area and the posterior language areas, including Wernicke's area and the primary auditory cortex.

Broca's Area

Broca's area, located in the inferior posterior frontal lobe, organizes the output of language. An expressive language deficit is recognized as the most common language impairment. A deficit in Broca's area tends to reduce speech to nouns and verbs only,

eliminating articles, and adverbs (Kean, 1977). Difficulty with repetition and naming is also evident, although object naming can be aided by prompting with sounds or context (Kohn & Goodglass, 1985). It should be noted that when an individual has a lesion in Broca's area, comprehension can be perfectly intact (Caramazza, Capitani, Rey, & Berndt, 2001). This often produces extreme frustration at their own inability to convey what they are thinking.

Wernicke's Area

Wernicke's area, positioned in the posterior section of the superior temporal gyrus, is involved in deciphering meaning from language. Children will often produce fluent and sometimes hyperfluent language when a deficit is found in this neuroanatomical structure; however, their speech is generally unintelligible and filled with paraphasia's that are semantic in nature (Ellis, Miller, & Sin, 1983). For example, they will substitute words for ones that they intend to speak (i.e., desk for table, blue for red, leg for hair) and will exhibit comprehension impairments in their own language and that of others.

Interestingly their articulation and diction may be very good even though the content can be comprehended as nonsensical by the listener (Ellis, Miller, & Sin, 1983). The result is often referred to as "word salad."

Many sources of evidence suggest that comprehension or the phonological stages of spoken word recognition are supported by neural systems in the superior temporal gyrus (STG) and superior temporal sulcus (STS). In neuroimaging studies, listening to speech activates the superior temporal lobe bilaterally and largely symmetrically (Binder et. al., 2000). Anterior temporal lobe (ATL) regions have also been implicated both in lexical-semantic and sentence-level processing (syntactic and/or semantic integration processes). An intricate interplay of all of these neural resources then facilitates the development of language as it unfolds in largely predictable stages.

TYPICAL LANGUAGE DEVELOPMENT

Infancy

Although a quite complex construct, language is simply defined as a form of communication which is based on a system of symbols. Most linguistics separate language into five systems of rules: phonology, morphology, syntax, semantics, and pragmatics. Interestingly, no matter what culture you are from and what language you speak, infants from all over the world follow a similar path of these systems in language development. According to some researchers, vocal learning begins in-utero with fetal exposure to prosody and affective qualities of the maternal voice (Locke, 1997; Mame, Friederici, Christophe, & Wormke, 2009). In their first few months, newborns are strongly oriented toward human face and voice, thus learning superficial voice characteristic, which assists them with acquiring first stereotyped utterances around the age of 5 – 7 months (Locke, 1997). Exposure to parental expressions, both verbal and nonverbal, continues to be important while infants learn to use communicative gestures and begin their lexical learning (Goldin-Meadow, 2014;

Locke, 1997). Perceiving and acquiring socially relevant cognitive linguistic operations, such as taking vocal turns with a care giver, gesturing communicatively, and mimicking ambient speech patterns, aids in this introduction to communication and word learning (Locke, 1997; Tsao, Liu, & Kuhl, 2004). Moreover, in the second part of the infant's first year he/she is able to recognize interruptions in the speech stream, thus gaining the means to break down speech into units based on its melodic qualities (Locke, 1997). During this time, the process of neural commitment occurs, which solidifies the infants' recognition and preference for the patterns and variations of their mother tongue (Kuhl, 2004). More specifically, Kuhl (1993, 2000) discovered that from birth to age 6 months, infants are hearing and learning all language sounds of the world. However, from 6 months on, infants begin to perceive the changes in their native language, and gradually lose the ability to recognize sounds from other languages. This change corresponds to neuronal maturational changes. Before neurons become highly specialized they have significant neuroplasticity referred to as equipotentiality. After a certain amount of specific stimulation (exposure to the primary language) they undergo some long-term changes. They become fine-tuned to primary language phonemes.

While infants make strides in developing their perception and reception of language, progress in their ability to express language is also being made. The initial stage of expressive language development is termed "babbling." Babbling describes the sounds babies produce to attract the attention of their parents or caregivers. These sounds can also take on the form of crying, cooing, and gestures. Even children with hearing impairments will make sounds vocally at their parents during the infancy stages (Bloom, 1998; Goldin-Meadow, 2006) suggesting a unified language capacity in all children.

From 8 to 12 months, infants begin to understand words. According to Menyuk, Liebergott, and Schultz (1995) when children reach their first birthday, they typically understand about 50 words. As such, receptive vocabulary far exceeds expressive vocabulary. Between 10 and 15 months, a typical milestone for an infant to utter their first spoken word takes place. In fact, this time frame is so genetically driven that significant delays in first word acquisition may suggest brain dysfunction and the possibility of some longer term issues. Additionally, this beginning of speech corresponds to growth of the left hemisphere and helps facilitate stimulation to the language areas of the brain. A child's first words are typically naming something important to them, such as "momma", "dada", "dog", "ball", or "cookie." These single words often have multiple meanings, such as "I want the ball" or "That is a ball." Once this first word is spoken, a child's vocabulary takes off – with the average 18 month-old being able to express approximately 50 and the average 2 year-old being able to express over 200 words.

Toddler/Preschool

By the time the child reaches 2 years of age, they are typically beginning to use two-word utterances. At this stage, a child's language appears to be telegraphic; short words without grammar markers (e.g., "see dog" and "give ice cream"). These first words and phrases are formulaic or holistic in nature and not subject to further analysis (Locke, 1997), yet at the same time phonetic learning is already taking place with the child being able to discriminate between phonemes more precisely than he/she will ever be able to do at later ages (Kuhl, 2004). After a certain amount of language exposure, the primary auditory cortex neurons

become highly specialized in decoding and discriminating language and nuisance. Unfortunately this occurs at the expense of the ability to proficiently hear and process phonemes of other languages. The inherent developmental neuroplasticity causes the relevant neurons to become maximally sensitive to the stimuli they are receiving, which are the sounds of the child's native language. If exposed to a second language before this process is complete the individual will develop a natural-like ability for both languages.

Phonetic learning strategies are eventually augmented and replaced by computational learning, which can help the child segment words into syllables (Kuhl, 2004; Locke, 1997). From this stage, children move quickly into the three, four, and five word sentences; taking them to the years of early elementary school. In addition, preschool children are able to analyze the structure of speech and begin to acquire grammatical ability, which provides the tools needed for morphology, phonology, syntax, and lexicon mastery (Locke, 1997). Equipped with these new skills, they experiences a burst in word learning and integration of this new knowledge (Locke, 1997). During this time, children are also exposed to rhymes, poems, songs, and silly sayings. This is the pre-literacy period where interaction with print-materials heightens and preschoolers begin to learn morphological rules such as plurals, present and past tense, prepositions, displacement, articles, and organization of sounds. It is typically during these years that language or speech difficulties become evident. In fact, children who do not have many print-related interactions during the preschool years have been shown to take longer developing literacy (Antonaci & O'Callaghan, 2006; Pressley, 2003).

Elementary School

By elementary school age (approximately 6 years old), children's vocabulary has reached a range of 8000 to 14000 words (Bloom, 2002). This translates into learning 5-8 new words a day from the ages of 1 to 6. When children enter school, the rate of lexical acquisition increases even further to an astonishing 22 new words per day. Of note, early vocabulary growth has been correlated with the quantity of speech that parents direct at their children (Huttenlocker, Haight, Bruk, Seltzer, & Lyons., 1991; Goldin-Meadow, 2014). Additionally, vocabulary, grammar, metalinguistic awareness, and pragmatics all greatly improve during the elementary years.

Reading is another language skill that begins to develop and strengthen when children are attending elementary school. Jeanne Chall (1979) devised a model which divides the development of reading skills into five stages from birth all the way through high school. Although the ages are approximate, they outline the developmental changes which occur when a child learns to read. While a great deal of discussion in the field focuses on identifying the dominant approach, there are two basic schools of thoughts on learning to read: whole-language and basic-skills-and-phonics. The whole-language approach asserts that reading instruction should parallel a child's natural language. Thus, children's reading materials should be whole so that the focus can be on meaning and comprehension (Goodman, 1986). Alternatively, the *basic-skills-and-phonics approach* asserts that reading should be taught by phonics and the rules for translating written symbols into sounds (Cunningham, 2005; Lane & Pullen, 2004). Although the debate over which approach is better remains, there is strong evidence that both together may serve the learner best (Durkin,

2004; Fox & Hull, 2002; Silva & Martins, 2003; Temple, Ogle, Crawford, & Freppon, 2005). Nonetheless, stressing both concepts equally in pedagogical methodologies does not diminish the importance of phonics in language development. As children mature, their social interactions increase, and the exposure to language and communication expands into new concepts and environments (Kuhl, 2004).

The cross-culturally normalized time-dependent phases of language development suggest that many of the developmental processes are likely genetically determined. Indeed, evidence from twin studies supports moderate influence of genetic factors on both language ability and disability for multiple skills areas (e.g., articulation, phonology, grammar, vocabulary, and verbal memory; Kovas et al., 2005; Trouton, Spinath, & Plomin, 2002). Conversely, research about critical periods in language development (Locke, 1997) indicates that many of the involved processes are not only genetically driven, but also experience-dependent and therefore co-determined by the degree of available environmental stimulation.

DISRUPTION OF LANGUAGE DEVELOPMENT

While the above pattern and types of learning describe the phases of typical language development, disruption in that process may lead to delays in acquiring specific language skills and eventually specific language impairments. Locke (1997) suggested that delays in analytical and computational processes which enable the discovery of regularities and thus promote phonology, morphology, and syntax can delay lexical learning. The neuroanatomical adaptations to such delays involve an increase in hemispheric symmetry by the recruitment of homologous right hemisphere structures. While atypically developing brain structures may fulfill a compensatory function, they may do so in a less than optimal way (Locke, 1997). The observation that infants and toddlers who undergo complete removal of the left hemisphere acquire or recover near-normal language suggests that the right hemisphere can take over most of the language functions of the left hemisphere provided the transfer of function happens early enough (Byrne and Gates, 1987), while the neurons still have a high level of neuroplasticity. Considerable clinical literature suggests that in these cases there is also a disruption in typical right hemisphere functions since that brain tissue has had to assume language functions at the expense of other functions.

Yet, children with speech and language impairments do not often show gross abnormalities when inspecting the brain (Snowling & Hayiou-Thomas, 2010). Nevertheless, some brain-based differences have been identified including anatomical differences in the perisylvian regions, such as asymmetry of plana temporal (right > left asymmetry; Leonard et al., 2002) and reduced or reversed asymmetry of Broca's area (De Fosse et al., 2004; Gauger, Lombardino, & Leonard, 1997). Further, language impairment has been associated with more widespread neural differences across frontal, temporal, parietal, and subcortical regions (Bishop & Snowling, 2004) and total cerebral volume reduction (Leonard et al., 2002; Trauner, Wulfeck, Tallal, & Hasselink, 2000) adding support to the theory that language is more complex than just a few neuroanatomical structures in the left hemisphere.

LANGUAGE IMPAIRMENTS AND DEFICITS

Specific Language Impairment Disorder (SLI)

Regardless of the cause of the delays, the resulting impairments often fall under one of the following diagnoses: SLI and Speech Sound Disorder (SSD). SLI is a neurodevelopmental disorder characterized by delays or significant deficits in language development in the absence of general cognitive problems, hearing impairments, psychiatric problems, or overt related neurological damage (Peterson & McGrath, 2009; Snowling & Hayiou-Thomas, 2010). Often, the classification occurs using the IQ discrepancy model. However, given the fundamental problem of IQ based discrepancies, this means that many children will have language deficits that do not specifically meet the definition, even if their language acquisition is far below their age and/or interfering with their daily functioning. According to the classification of language impairment, the prevalence rates range between 3% to 8% (Tomblin et. al., 1997).

Speech Sound Disorder (SSD)

Unlike SLI, SSD is classified by age, rather than the IQ discrepancy model which may be more practical in regard to identification and classification. Children are considered to meet the diagnosis of SSD if they substitute or omit sounds from words more than their same-age peers; especially, if their speech production errors interfere with their intelligibility (Peterson & McGrath, 2009). The prevalence rate for SSD is lower at 3.8% (Beitchman, Nair, Clegg, & Patel, 1986). Both disorders have been linked to genetics; however, there appears to be a strong environmental factor involving both home language and the literacy environment. Children with these language deficits may either have a family history of language impairments, contributing environmental or familial issues, an acquired brain dysfunction, or some combination of these factors. In fact, research has shown that children who enter elementary school with a small vocabulary are at risk of developing reading deficits (Berko & Gleason, 2005). Similarly, when children are not exposed to good phonic instruction during the early elementary years, they are less likely to develop appropriate decoding skills; resulting in spending more time sounding words out, than comprehending what they read (Stanovich, 1994).

For those who do not develop language in a typical fashion, the Critical Period Hypothesis (CPH; Lenneberg, 1967; Penfield & Roberts, 1959) for language development becomes very important. According to the CPH, there are constraints in the acquisition of first language. Specifically, if language is not acquired in a time expected manner, some aspects of language may never be optimally achieved. The CPH has garnered substantial empirical support, especially in the study of abnormal development, for instance with language acquisition in Down syndrome (Lenneberg, 1967) and autism (Moore & Sheik, 1971). However, given that language can still develop, just not as ideally as if acquired in the requisite time frame, some researchers argue that these periods of essential learning and exposure would be more accurately described as sensitive rather than critical (Bench, 1971; Redmond, 1993).

Given this differentiation of terminology, two versions of the CPH have emerged: the rigid version and the flexible version (Alghizzi, 2014; Redmond, 1993) also referred to as a strong and weak version. Those that subscribe to the rigid version believe that if an individual was unable to acquire primary language during the critical period, a functional level of language would never be attained, no matter what type of intervention or language exposure occurs (Alghizzi, 2014; Redmond, 1993; Seigler, 1981; Singleton, 1989). Supporters of the flexible version theorize that while the emergence of language should start during the critical period, language learning can still occur even after the critical period is closed, even though the affected individuals will likely not achieve the same language level as typically developing peers (Alghizzi, 2014; Redmond, 1993; Scovel, 1988). Regardless of one's position on the flexible version or rigid version of the CPH, there continues to be precedence for early intensive interventions for children with speech-language impairments, developmental disabilities, and autism spectrum disorders. Some clinicians prefer to consider a moderated conceptualization of the CPH. Specifically, they purport that treatments for language delays require an increasing amount of time and perhaps more diverse planning as the time post critical period grows.

Although acquired (ABI) or traumatic brain injury (TBI) is not the focus of this chapter, language development and brain dysfunction cannot be discussed without a brief notation regarding aphasia's resulting from brain injury. Classification of aphasia's remains a common debate in the field of neuropsychology. Among those clinicians and researchers who have been willing to categorize language deficits, most agree to either a two-term aphasia classification (i.e., expressive and receptive) or a six-term classification (i.e., Broca's, Wernicke's, Conduction, Anomic, Transcortical Motor, and Transcortical Sensory). The six-term classification developed from the work of Geschwind (1970) and Goodglass and Kaplan (1972) and is often referred to as the Boston classification. The Boston classification has increased in popularity due to its related aspects to lesions at particular sites on the cerebral cortex lending it diagnostic validity (Beaumont, 2008).

INTERVENTIONS

Spoken language disorders impact children with a variety of issues, including intellectual disability, global developmental delay, hearing or other sensory impairment, motor dysfunction, or a variety of other mental disorders or medical conditions. A range of treatment options is available for language disorders, such as behavioral interventions, language interventions, narrative interventions, parent-training interventions, social skills and social communication interventions, relationship-based interventions, and sensory based interventions. Empirical support for these treatments is variable depending on which intervention is utilized. In many of the individuals receiving language interventions, it is clear that other aspects of cognition and socialization have also been affected. Though speculative, some clinicians suspect that the delayed language, if significant, is limiting the development of other abilities, such as social skills. Moreover, when verbal language development lags there is certainly the possibility for the increase in other perhaps far less adaptive ways of communication.

There are significant precedents for early intensive interventions for children with speech-language impairments, developmental disabilities, and autism spectrum disorders. Whether interventions are behaviorally based or provided by a speech-language pathologist, the most successfully used interventions share many commonalities. For example, they tend to involve the whole family (Koegel, 2000; Koegel, Koegel, Frea & Smith, 1995; Robbins, 2009). Due to the fact that parents spend more time with their children during the days, evenings, and weekends, they are able to provide more consistent and time-intensive interventions for their children (Koegel et al., 1995). Furthermore, a family-centered approach allows for the family to be involved in multiple aspects of care and treatment (Crais, Poston Roy & Free, 2006). While incorporating family members is essential in the success of any early intervention program, clinicians should be mindful of how placing additional demands on the family may increase parental stress (Koegel, 2000). Research indicates that high levels of parental stress actually minimize or undermine the effectiveness of early interventions (Osborne, McHugh, Saunders, & Reed, 2007). Conversely, by being responsive to family needs in creating an intervention program, parental stress should, in fact, decrease (Koegel, 2000; Moes, 1995). Thus, family-based interventions should be designed to fit into the families' specific lifestyles and routines, as opposed to requiring parents to carve out time to work one-on-one with their child (Koegel, 2000). Programs that allow teaching to occur on a continual basis throughout the day result in even more gains in the frequency of communication by the child (Koegel, 2000; Koegel, Bimbela & Schreibman, 1996; Schreibman, Kaneko & Koegel, 1991).

Another hallmark of effective therapies is cultural sensitivity. With the change in the demographic composition of the United States over the past decades, professionals are currently working with children from increasingly more diverse cultures (Hanson & Lynch, 2004). As a result, programs incorporating family should be culturally and linguistically sensitive and responsive (Koegel, 2000; Robbins, 2009). In addition, many successful interventions include coordinated efforts of multiple stakeholders (i.e., service providers; Robbins, 2009), as well as trained volunteers and consultants (Koegel, Koegel, & Carter, 1999) and care-givers (Koegel & Koegel, 2006; Roberts & Kaiser, 2011). Effective treatment programs also tend to promote generalization to the natural environment and emphasize best practices.

Behavioral Interventions

All behavioral interventions have the goal of decreasing disruptive or problem behaviors while providing functional and adaptive replacement behaviors. Common behavioral interventions include Discrete Trial Training (DTT; Bogin, Sullivan, Rogers, & Stabel, 2010), Functional Communication Training (FCT; Carr & Durand, 1985), Lovaas model (Lovaas, 1987), Milieu therapy, and Pivotal Response Treatment (PRT; Koegel & Koegel, 2006).

DTT, the Lovaas model, and the University of California, Los Angeles (UCLA) Young Autism Project method are often used in conjunction with one another and considered under the larger term of Applied Behavioral Analysis (ABA). In a review of behavioral interventions conducted by the Agency for Healthcare Research and Quality (AHRQ; 2014), results of 25 studies of Early Intensive Behavioral Interventions (EIBI) utilized with children diagnosed with autism spectrum disorders were reviewed. Results indicated a positive effect

of EIBI ABA-based interventions on language and communication skills (AHRQ, 2014). Although the impact on the specific domain language was variable in these studies (expressive vs receptive), there is evidence of an overall positive effect (AHRQ, 2014). Furthermore, many of these studies indicated that ABA based treatments positively influenced social skills (AHRQ, 2014). Reviews of the literature found support for the success of the Lovaas model in improving many of the core symptoms associated with autism and autism spectrum disorders; however, many of the studies have inconsistent methods, few participants, or relatively little follow up (Ospina et. al., 2008). Language and communication, particularly in social contexts, are often reciprocal in their developmental stimulation. In the context of Autism, individuals are not practicing their language socially and treatment, no matter how efficacious, cannot take the place of the thousands of hours typical developing children spend in social conversation and thinking.

Functional Communication Training (FCT) is a behavioral intervention first reported by Carr and Durand (1985). This intervention proposes that problem behaviors can be eliminated through extinction; through behavioral principles, alternative and more appropriate forms of communication are taught as replacement behaviors (Carr & Durand, 1985). Based on their report, Carr and Durand successfully increased communication, which in turn assisted in reducing problem behaviors (Carr & Durand, 1985). Other empirical studies have provided support for FCT as successful in reducing challenging and problem behaviors, while increasing language (Durand, 1990; Durand & Merges, 2001).

Milieu therapy and training incorporates naturalistic interventions to address language. Interventions included in this area include milieu teaching (MT; Hancock & Kaiser, 2002), prelinguistic milieu teaching (PMT; Yoder & Warrant, 1998), and enhanced milieu teaching (EMT; Hancock & Kaiser, 2002). These methods are incorporated into the natural environment in order to present communication and language opportunities throughout the day, as opposed to occurring only during designated therapeutic intervention time. There is evidence that utilization of naturalistic sign and language interventions improves communication (Fey, Yoder, Warren, & Bredin-Oja, 2013; Wright et al., 2013), though support is limited.

Pivotal Response Training (Koegel & Koegel, 2006) is designed to increase functional language during play-based, child-initiated behavioral intervention. As opposed to other ABA based interventions, PRT focuses on reinforcement that is natural and occurs after a meaningful attempt (Koegel & Koegel, 2006). PRT incorporates several pivotal areas to address behaviors. Initially, research focused on responsivity to multiple cues, increasing motivation, and addressing self-management (Koegel, Koegel, & Harrower, 1999). By reinforcing attempts of utilizing language (Koegel, O'Dell, & Dunlap, 1988) and using natural reinforcers (Koegl & Williams, 1980) increases in functional language are thought to occur. There is evidence to support that PRT positively impacts communication and social interactions (Koegel, Koegel, & Harrower, 1999; Koegel, Koegel, & Surratt, 1992; Koegel, O'Dell & Koegel, 1987; Ospina et al., 2008), as well as improvements in untargeted areas (Koegel, Koegel, & McNerney, 2001).

Language Interventions

According to American Speech-Language-Hearing Association (ASHA; “Spoken Language Disorders,” 2015), language interventions include clinician-oriented, child-oriented, and hybrid approaches. While gaps exist in the literature regarding the effectiveness of language interventions (Cirrin & Gillam, 2008; Kamhi, 2014; Law, Garrett, & Nye, 2004; Wallach, 2014), the principles and areas addressed by them are consistent (Fey, Long, & Finestack, 2003; Kamhi, 2014). In *clinician-oriented approaches*, the clinician chooses the treatment goals and utilizes operant principles to teach language (“Spoken Language Disorders,” 2015). In *child-oriented* approaches, the clinician incorporates language goals into child-led activities that occur in a more natural environment (“Spoken Language Disorders,” 2015). In the *hybrid approaches*, the clinician utilizes naturalistic activities to promote language opportunities (“Spoken Language Disorders,” 2015).

Regardless of age, language interventions focus on phonology, morphology and syntax, and pragmatics. In preschool age children, phonology interventions address intelligibility, increase phonological awareness skills (e.g., rhyming, blending, segmenting, deletion, etc.), build vocabulary to approach the vocabulary of language-typical peers, and increase understanding of semantic relationships. Morphology and syntax interventions in preschool age children examine how to facilitate acquisition of morphemes, increase sentence length and sentence complexity, and use varying sentence type. Pragmatic interventions strive to increase imaginative play skills that utilize language, improving conversational skills, and developing story-telling and narrative skills.

Interventions for school age children target skills necessary for success in the academic environment. The same areas are addressed as in preschool age children with addition of intervention goals targeting the skills needed for academic success. Phonological interventions aim to improve phonological awareness skills. Semantic interventions emphasize knowledge and depth of vocabulary and understanding and recognizing ambiguities in language. Additionally, they facilitate comprehension and address paraphrasing as opposed to verbatim repetition. According to the ASHA, morphology and syntax interventions focus on increasing and advancing morphology; analyzing complex words; formulating compound sentence structures; and utilizing rules of grammar to correct errors (“Spoken Language Disorders,” 2015). Pragmatic interventions work to incorporate politeness; increase appropriate contributions to classroom and social discourse; and teach matching language to situations, while recognizing what not to say (“Spoken Language Disorders,” 2015).

Parent-Mediated Interventions

These therapies require the direct involvement of parents who themselves implement individualized interventions. Many of these interventions are play-based in nature, requiring parents to pay attention to their child’s attention and activity during play (Siller & Sigman, 2008; Siller, Hutman, & Sigman, 2013). Reviews of studies examining parent training found support for language improvement (AHRQ, 2014; Roberts & Kaiser, 2011); especially when parents are responsive to child attention during play (Siller & Sigman, 2008, Siller, Hutman, & Sigman, 2013). However, specific interventions employed in the reviewed studies were

inconsistent across the studies reviewed, which indicates the need for replication of results when examining consistent parent-mediated interventions (AHRQ, 2014).

Social Skills and Social Communication Interventions

Approaches that utilize social skills and social communication aim to increase social skills and promote social competence (Cook, Gresham, Kern, Barreras, Thornton, & Crews, 2008). The empirical support for these approaches is limited (AHRQ, 2014), though successful strategies include a combination of social modeling, coaching, and encouraging practice (Cumming, Strnadová, & Dowse, 2014; Gresham, 2002).

Relationship-Based Interventions

Floortime (Greenspan, Weider & Simons, 1998) is a relationship-based intervention designed to support the parent-child relationship by encouraging the child to interact with parents through play. The Developmental, Individual Difference, Relationship-based (DIR) Floortime Model focuses on addressing individual differences by examining how a child processes and understands new experiences, reacts to sound, comprehends visual experience, plans actions, and responds and handles relationships (Greenspan, 2006). Little empirical support exists for Floortime (Mesibov & Shea, 2011).

Sensory-Based Interventions

Interventions based on principles of sensory integration theory to treat sensory dysfunction fall in this category, including Auditory Integration Therapy (AIT), otherwise known as the Bérard method (Bérard & Brockett, 2011). AIT utilizes middle ear muscles and auditory nervous system to retrain a disorganized auditory system, regardless of hearing ability (Bérard & Brockett, 2011). Empirical support is limited for the effectiveness of AIT (Al-Ayadhi, Al-Dress, & Al-Arfaj, 2013; van der Meer, Sigafos, O'Reilly, & Lancioni, 2011).

In summary, effective speech interventions should be empirically supported, and many of those listed above have considerable research backing (Bernstein Ratner, 2006; Cirrin & Gillam, 2008; Gillam & Gillam, 2006; Kamhi, 2006, 2011, 2014; Wallach, 2014). Furthermore, effective speech interventions should aim for children to become actively engaged in learning (Wallach, 2014), while assisting them in increasing communication strategies (Roth & Worthington, 2015). In order to attain active engagement of the student, speech interventions need to be interactive and dynamic (Roth & Worthington, 2015). The most successful speech interventions are those that address the specific and individual deficits of the child (Kamhi, 2014; Roth & Worthington, 2015; Wallach, 2014). Although interventions may start very specific and mechanistic, the ideal is that interventions evolve into more naturalist communication. Regardless of age, all therapies should also address all of the skill areas in structural language, including phonology, semantics, morphology, and syntax, as well as the pragmatic use of language (Weismer, 2014). Oftentimes, interventions

utilized to address language and communications skills have variable results regarding generalization to the natural environment (Kamhi, 2014). Thus, the most successful interventions tend to be the ones that promote such a generalization. Many speech and language interventions and behavioral interventions attempt to address the issue of generalizing the intervention gains by taking place in the natural environment, as in child-oriented language approaches (“Spoken Language,” 2015), and focusing on pivotal areas to increase improvements in untargeted areas (Koegel & Koegel, 2006; Koegel, Koegel, & Harrower, 1999). Attempts continue to close gaps that are present in the literature regarding speech and language interventions (Kamhi, 2014; Wallach, 2014). Expanding the empirical evidence foundation for language deficit treatments is imperative for the continued improvement of children’s ability to acquire language, regardless of the reason for their deficit.

CONCLUSION

Language is a genetically driven and environmentally dependent skill that helps facilitate many other aspects of brain functioning. It comprises a set of skills that are distributed throughout the left hemisphere, but largely in the perisylvian area. Human language development is so well researched that deviations in typical developmental patterns can be very predictive of specific brain dysfunction. When language skills become impaired, early and specific treatment has been shown to effectively treat many language impairments. Language assessment and treatments continue to evolve.

Chapter 4

ATYPICAL LANGUAGE DEVELOPMENT AND PSYCHOPATHOLOGICAL RISK: A TYPICAL NEUROPSYCHIATRIC PROBLEM?

National Neurological Institute C. Mondino, Pavia, Italy

ABSTRACT

Cohen and coworkers were the first to demonstrate the presence of significant difficulties in language development and/or of the evolutive trajectory of this function in subjects evaluated in their adolescence for serious psychopathology. Subsequent longitudinal studies showed that children with language and communication disorders are at risk of having social, behavioral and emotional difficulties in adolescence and adult age.

A number of different mechanisms can be invoked to explain this association. First, language is a powerful tool for processing difficulties both in the relational contest and related to the so-called “social problem solving”. Others believe that the defect in mentalization associated with a frailty of executive functions might produce a decline of language skills in individuals predisposed to develop a psychopathological disorder. Still others point out that it is possible that the deficits in language make psychopathological problems that otherwise would have remained sub-threshold more evident and serious, as they reduce the relational exchanges. Finally, it has been hypothesized that there may be other mechanisms common to both the difficulty of the language and the psychopathological disorders, in terms of both genetic aspects and neurocognitive functions (e.g., working memory deficits).

In any case, it is evident that an atypical functioning of a given subject in the field of language is a relevant factor for the treatment, especially when the treatment method largely uses the word to induce a change in mental functioning (as in most psychotherapies).

INTRODUCTION

Language impairments in their various forms affect 3–7% of the population (Norbury & Paul, 2013). In Italy, a difficulty in acquiring age-adequate language skills is the most frequent reason for a neuropsychiatric consultation in pre-schoolers, although at least half of these children present also other significant symptoms (in terms of psychomotor development and/or of emotional and behavioral functioning).

Despite their relevance for children wellbeing and their cost for the health system, language impairments receive very little public attention, research interest or research funding (Bishop, 2010). This is even more surprising given that language is central to our everyday lives; we use language to learn and to work, to communicate with our friends and loved ones and to access leisure activities such as reading and television. Additionally, language is a fantastic resource for problem solving, negotiating and managing our thoughts, feelings and behavior.

Longitudinal studies of community and speech-language clinic samples have shown that language problems identified early in childhood not rarely persist into adolescence (e.g., Beitchman et al., 1996; Conti-Ramsden & Botting, 2008; Voci et al., 2006). Moreover, adolescents with a history of language impairment often experience social stress reflected in poorer quality of friendships, social relationships, and pragmatic communication skills (e.g., Durkin & Conti-Ramsden, 2007; Wadman et al., 2011) and are especially prone to emotional and social difficulties (e.g., St. Clair et al., 2011; Voci et al., 2006). Furthermore, youth diagnosed with language impairment show higher rates of ADHD, anxiety, depression, conduct disorder, and delinquency (Cohen et al., 1998; Brownlie et al., 2004; Snowling et al., 2006).

One of the most significant studies provides information on the Danish population: an atypical development of language skills was a strong predictor of Neurodevelopmental Disorders (OR: 5.9), but also of children and adolescent psychiatric disorders (OR: 3.3) (Skovgard, 2010).

While core elements of structural language develop in childhood, certain aspects of language show marked development during adolescence. These include verbal reasoning, understanding and using higher order language, and language required for social interactions.

Cohen et al. assessed 144 adolescents referred to mental health services and 186 non-referred peers. Overall, the referred group had significantly lower scores on standardized tests of structural and pragmatic language abilities (which they named higher order language abilities), with 45% of the group meeting criteria for language impairment. Lower non-verbal IQ, poorer working memory, and lower levels of maternal education increased risk for language impairment in this group (Cohen et al., 2013).

During the transition to adolescence, demands on language grow in complexity and abstractness (Power et al., 2001; Nippold & Taylor, 2002). Lazar and colleagues (Lazar et al., 1989) showed that utterances by classroom teachers that contain at least one type of figurative language increased from 5% in kindergarten (age 5–6 years) to 20% in grade 8 (age 13–14 years). While young children are capable of making inferences, they typically do not do so unless prompted.

Thus, problems with higher order language may not be evident in younger samples, even among children with diagnosed language impairment. A case in point are two studies by Bishop and Edmundson (1987) that examined children's language at four important

developmental transition points. Among children diagnosed as having a structural language impairment at the age of 4 years, 66% no longer met criterion for language impairment at 5½ years. Nevertheless, in a follow-up study into adolescence, even the good outcome group showed subtle but significant deficits compared with controls on tasks tapping verbal short-term memory, and phonological skills. These children also showed problems with inferential reading comprehension, a skill that requires higher order language abilities (Stothard et al., 1998; Snowling et al., 2000). Such problems clearly occurred in adolescence even when more basic structural language impairments seem to have resolved.

Higher order language also has both direct and indirect effects on psychosocial development. In terms of direct effects, language is a means of analysis and self-control by way of both internal language and discussions with others (e.g., Bishop, 2003). Moreover, through coherent and organized discussions of feelings, thoughts and ideas, adolescents gain a sense of both self-expression and self-control. In terms of indirect effects, adolescents with higher order language problems who struggle to keep up with increasingly demanding schoolwork and who encounter difficulties in relationships often suffer in terms of their feelings of self-efficacy and self-esteem (Levine, 1999). In addition, they may become more isolated to hide difficulties from peers and adopt ineffective defenses to deal with these problems. Thus, it is likely that adolescents who do not have the age appropriate higher order language skills to succeed in school, present and flexibly discuss a point of view and negotiate outcomes, and engage in social repartee with peers and adults will be at a disadvantage.

Clinic-referred youth in this study are three times (45%) more likely than comparison youth (15%) to meet criterion for a Higher Order Language Impairment. Research has shown that youth presenting for assessment and treatment of mental health problems often are described as purposefully noncompliant to directions, oppositional, lazy, and lacking interest in school (Cohen et al., 1998). These behaviors typically are interpreted as willful rather than being linked to inadequate communication and comprehension skills and working memory problems. For instance, clinic referred youth may fail to complete assignments or projects, or answer examination questions correctly because it is hard for them to process and maintain in working memory a chain of instructions or information. They also may have difficulty understanding content material or what is expected of them. In spite of these well established associations, language impairment is often overlooked in the assessment of children and youth presenting for mental health services (e.g., Toppelberg & Shapiro, 2000; Cohen et al., 1998).

In this context, it is also important to highlight that problems with higher order language were not limited to the clinic-referred sample but also observed, albeit less frequently, in the comparison group. Moreover, the correlates of higher order language impairment in the two groups are similar. The high school curriculum and teachers need to be sensitive to the higher order language needs of adolescents, which may be overlooked or misinterpreted. Clearly there are many youth who would benefit from help in understanding the expectations of assignments and becoming more skilled at interpreting literature and discourse where figurative language is embedded. However, there are fewer services for language impairment or language related learning disabilities for this age group in high schools than for younger preschool children or children in the elementary grades (e.g., Dockrell et al., 2006).

These findings resonate with earlier seminal work by the research group lead by Cohen, demonstrating high proportions of children referred to child and mental health services for

emotional and behavioral problems experienced concomitant language impairments (Cohen et al., 1998). These authors have shown that a sizeable proportion of children referred for assessment and treatment of social and/or emotional problems have a structural language impairment with estimates ranging from 50% to 80%. Moreover, for many children language impairment remains unsuspected unless a routine examination is done (Cohen et al., 1998).

The findings are also in accord with longitudinal studies of children with identified language and communication impairments, who are at elevated risk for social, emotional and behavioral difficulties in adolescence and adulthood (Snowling et al., 2006; St Clair et al., 2011).

MODELS TO UNDERSTAND THE LANGUAGE – PSYCHOPATHOLOGY CONNECTION

Considered separately, clinically significant behavior problems are estimated to affect 10% to 15% of preschool children (Campbell, 1995). Other estimates suggest that nearly 17% of preschool children meet criteria for oppositional defiant disorder and that 20% experience moderate levels of externalizing symptoms (Pianta & Caldwell, 1990; Lavigne et al., 1996).

Although some children evidence decreases in externalizing behaviors over time, nearly 20% of children with initially moderate or high levels of aggressive behavior follow a fairly stable course over time, with negative outcomes (e.g., social maladjustment, academic problems) apparent at 12 years of age (Campbell et al., 2006).

Externalizing behavior problems are associated with additional maladaptive correlates, including peer rejection, social skill deficits, academic difficulties, and high rates of expulsion and suspension from preschool and day care (Qi & Kaiser, 2003; Gilliam & Shahar, 2006).

Estimates of language delay range from 12.5% to 15% among older infants and toddlers, and 18% to 28% among 30–39-month-olds (Horwitz et al., 2003). Children with early language difficulties experience long-term adverse outcomes, including demoralization, higher levels of grade retention, and lowered academic performance, even subsequent to the resolution of their language problems (Catts, 1993; Benner et al., 2002; Snowling et al., 2006; Harrison et al., 2009).

Given that both language difficulties and externalizing behaviors are associated with negative correlates and sequelae, examining processes that may underlie co-occurring linguistic and behavioral difficulties could inform etiological and intervention models at a time when these processes are amenable to intervention, and prior to the development of additional sequelae.

Notably, two studies found that externalizing behavior problems were not reliably correlated with expressive language delay until after 30 months of age (Horwitz et al., 2003; Tervo, 2007). During this developmental period, language difficulties (receptive and expressive) are most likely associated with deficits in social competence, as opposed to externalizing behaviors (Caulfield et al., 1991; Irwin et al., 2002; Horwitz et al., 2003; Ross & Weinberg, 2006; Tervo, 2007). Thus, given that decreased social competence is a common correlate of language delay among children from birth to age three, limited social–linguistic opportunities resulting in diminished social competence may mediate the pathway between early language difficulties and later behavior problems.

The development of linguistic competencies is critical for early school success. School entry represents a significant developmental milestone for preschoolers, who must form new relationships outside of the family, adjust to the expectations of teachers and classroom routines, follow directions and interact with peers during learning and play (Olson & Hoza, 1993; Mendez et al., 2002). Thus, among the most important tasks for preschoolers is the development of self-regulatory strategies and positive peer relations (Olson & Hoza, 1993; Liebermann et al., 2007). Typically developing children's linguistic and communicative development forms the basis for meta-communication about play, planning for play, and the execution of complex social pretend play (Howes & Lee, 2006). Between 36 months and 48 months of age, preschoolers' development of self-regulatory systems is characterized by dramatic improvements in error detection and ability to inhibit actions, which coincides with the development of frontal brain structures that occurs during this developmental period (Jones et al., 2003).

One consistent research finding is that preschool-aged children with language difficulties continue to evidence deficits in social skills (Qi & Kaiser, 2004; Stanton-Chapman et al., 2007), suggesting some continuity in the correlates of language difficulties from the toddler to preschool period. However, emotional and behavioral problems also become reliably and positively associated with language difficulties during preschool (Beitchman et al., 1989; Willinger et al., 2003; Qi & Kaiser, 2004; McCabe, 2005; Stanton-Chapman et al., 2007), with more severe behavioral problems noted among children with receptive or pervasive language difficulties, compared to expressive language impairment (Beitchman et al., 1989; Estrem, 2005; McCabe, 2005; van Daal et al., 2007). Language difficulties may confer non-specific risk for the development of behavioral problems by limiting children's exposure to social-linguistic opportunities or through other mediating variables. Thus, consideration of additional child-specific and contextual processes that may mediate or moderate these relations, and thereby contribute to particular outcomes, is necessary.

Despite the well-documented comorbidity between linguistic and behavioral difficulties, the potential mechanisms underlying this relation are not well understood. At least three explanations have been proposed for their co-occurrence (Schoenfeld et al., 1988; Dionne et al., 2003; Willinger et al., 2003). First, language difficulties may confer risk for behavior problems. For example, children may react with frustration and engage in problematic behaviors when they are unable to communicate effectively with others. In support of this explanation, two studies have reported that lower levels of early language skills temporally preceded the development of behavioral problems (Fagan & Iglesias, 2000; Brownlie et al., 2004).

Second, behavior problems may interfere with the development and acquisition of developmentally relevant language abilities and thus contribute to language difficulties.

Third, the association between behaviour problems and language difficulties may stem from shared etiologies or risk processes (Gilliam & de Mesquita, 2000). These three potential explanations often are discussed as mutually exclusive, competing explanations (e.g., Pine et al., 1997). However, given the heterogeneity of the population of children with comorbid linguistic and behavioral difficulties, it is unlikely that there is a single explanation for the causal mechanisms underlying this comorbidity (Stevenson, 1996). Rather than ascertaining which explanation is most valid, the goal of future research endeavors could be to ascertain which explanation(s) hold true among which children. A developmental psychopathology perspective provides one potential framework to facilitate this goal.

A developmental psychopathology perspective in fact can be used as a unifying framework from which to examine questions concerning the development of complex clinical phenomena (Rutter & Sroufe, 2000; Cicchetti & Toth, 2009; Drabick, 2009), and often includes consideration of typical and atypical development, underlying developmental processes, and transactional relations across multiple domains of risk and protective factors. Given that the associations between language difficulties and behavior problems likely differ based on a number of factors (e.g., type of language difficulties, developmental period, timing of language and behavior problems, and moderating variables at the individual and contextual levels), consideration of these developmental psychopathology principles may illuminate the nature of the interrelations between language difficulties and behavior problems.

Moreover, it is possible that developmental processes underlying the development of comorbidity may vary by sex, especially given: (1) higher rates of behavior problems and language difficulties among boys (Campbell, 2002; Horwitz et al., 2003), and (2) sex differences in interrelations among risk factors for behavior problems (Blatt-Eisengart et al., 2009). The empirical literature however has not yet provided sufficient evidence to inform separate models for boys and girls.

From a neuropsychological perspective, most research has focused on the possible significance of working memory deficits. Working memory involves the storage and manipulation of information so that this information can guide subsequent responses (Hongwanishkul et al., 2005), and thus is important for verbal and behavioral output. In general, working memory is positively correlated with language achievement and production of complex spoken language (Adams & Gathercole, 1995; Wolfe & Bell, 2004); moreover, phonological working memory deficits have been well documented among children with language difficulties (Gathercole & Baddeley, 1990; Baddeley et al., 1998). Preschoolers' working memory prospectively predicts vocabulary acquisition (Gathercole & Baddeley, 1989; Gathercole et al., 1992; Leclercq & Majerus, 2010) and is positively associated with spoken language comprehension, longer utterances, syntactic diversity, and lexical-semantic abilities (Adams et al., 1999; Adams & Gathercole, 2000; van Daal et al., 2008). The link between phonological working memory and vocabulary seems to be strongest in early childhood (Gathercole et al., 2005), which supports the inclusion of working memory in models focusing on word learning

during this developmental stage. Given phonological working memory's importance for recognizing and remembering phonemes, words, and phrases (Baddeley et al., 1998; Bannard & Matthews, 2008), working memory may be particularly important for processing simultaneous situational demands and limiting phonological memory decay when children are faced with challenging linguistic tasks (e.g., monitoring conversations, conversing, and playing simultaneously; Gillam et al., 1998). Poor working memory may make conversational exchanges challenging, possibly putting children at additional risk for missed social-linguistic opportunities and peer exclusion.

Working memory performance also has been linked to externalizing behavior problems, although in the externalizing literature, working memory is often studied under the umbrella term of executive function (Senn et al., 2004). Several studies have demonstrated negative associations between disruptive behaviors and: (1) executive function performance among preschoolers (Cole et al., 1993; Hughes et al., 2000; Hughes & Ensor, 2008; Bierman et al., 2009), and (2) poor working memory (Hooper et al., 2003; Aronen et al., 2005; Ripley & Yuil, 2005). Deficits in working memory may interfere with children's ability to remember

requests, follow directions, complete multi-step tasks, and engage in problem-solving skills, each of which may confer risk for behavior problems (Gathercole et al., 2008). Taken together, these results establish an association between working memory and both language difficulties and behavior problems. Another key factor to be included in any developmental model is temperament, which can be defined as the basic, probably genetically determined, predisposition to develop a pattern of psychological functioning. Although temperament is to be seen as a predisposition, as the environment can shape the final personality in a large and significant way, difficult temperament has been shown to confer risk for externalizing behavior problems among young children (e.g., Rothbart & Bates, 1998; Campbell, 2002; Sanson et al., 2004). Studies assessing individual dimensions of difficult temperament have demonstrated direct links between behavior problems and: (1) soothability and anger (Szabó et al., 2008), (2) impulsivity and anger (Karreman et al., 2010), and (3) activity, low adaptability, and negative affect/emotionality (De Pauw et al., 2009). Among preschool-aged children, proneness to anger is associated with externalizing behavior problems (Rothbart et al., 2000; Eisenberg et al., 2001; Rothbart et al., 2001; Hayden et al., 2005) and low levels of prosocial behaviors (Denham, 1986). With regard to children's language development, lower levels of linguistic mastery have been reported among children with difficult temperament (Slomkowski et al., 1992; Dixon & Shore, 1997; Dixon & Smith, 2000; Noel et al., 2008).

Researchers have hypothesized that more flexible and easygoing temperamental styles promote parent–child interactions that are conducive to learning words and allow parents to scaffold their children's emerging language skills (Noel et al., 2008). Thus, both working memory deficits and dimensions of difficult temperament, particularly a tendency to experience anger/frustration, may predispose young children to both externalizing behavior problems and disruptions in their language development, and consequently are conceptualized as shared risk factors for linguistic and behavioral comorbidity.

It is worth noting, however, that any multilevel, ecological model of development (e.g., Bronfenbrenner, 1979) indicates that child and contextual risk factors exert shared and interactive effects on children's outcomes (Drabick, 2009; Rutter & Sroufe, 2000). Therefore, children's immediate environmental contexts are likely to influence whether – and to what extent – linguistic, behavioral, or other risk processes lead to co-occurring linguistic and behavioral difficulties. Broadly speaking, qualities of the parent–child interactional and linguistic context represent significant sources of variability in explaining the development of comorbid language and behavior problems and may be linked to risk or resilience for this comorbid condition. For example, among children with either behavioural or linguistic difficulties, responsive parent–child interactions and/or higher levels of linguistic expressiveness in the home may promote resilience from co-occurring language and behaviour problems, whereas problematic parent–child interactions and low levels of linguistic expressiveness in the home may contribute to the development of co-occurring language and behaviour problems. Another significant contextual / environmental factor to be discussed is the interaction with peers. Children's engagement in play (e.g., prosocial, interactive, pretend play) has been linked to positive socio-emotional development (Fisher, 1992; Gagnon & Nagle, 2004), including stronger self-regulatory skills (Whitebread et al., 2009), higher social engagement, and lower levels of aggressive behaviours (Fantuzzo et al., 2004). However, children with language difficulties are often poorly equipped to engage in socially competent and interactive peer play, which is associated with multiple linguistic competencies (Craig-Unkefer & Kaiser, 2002), including higher concurrent levels of

receptive and expressive vocabulary (Mendez et al., 2002; Fantuzzo et al., 2004; Cohen & Mendez, 2009). Children with language difficulties are chosen less often as playmates for social pretend play activities (Gertner et al., 1994) and are less able to join ongoing play (Craig & Washington, 1993). Exclusion from peer play is likely to further intensify the social–linguistic delays of language-impaired children (Rice, 1993) and increase the likelihood that they will engage in aggressive or disruptive behaviors to achieve their interpersonal goals (Coie & Kupersmidt, 1983; Fantuzzo et al., 2004). Overall, these results suggest that limited opportunities for language-mediated social development may confer risk for behavior problems in the context of language difficulties. Putting together most of these aspects in a developmental model, Carpenter and Drabick (2011) suggested that difficult temperament and deficits in working memory act as initiating factors in the pathway that may culminate in comorbid language and behavior problems. Specifically, children who are temperamentally prone to anger and frustration may be more likely to act out behaviorally, and to evidence difficulty participating in early academic and social interactions that would promote language skills. Poor working memory may preclude or lessen children’s abilities to be compliant with adult requests and to follow complex directions, as well as children’s acquisition of vocabulary words and memory for phonemes. However, these authors noted that associations among these risk factors and comorbid linguistic and behavioral difficulties depend on moderating contextual and child-specific factors, which may exacerbate risk or promote resilience. Specifically, children’s emotion regulation capacities, parents’ engagement in linguistically stimulating activities, and the quality of parent–child interactions are hypothesized to be significant moderators of these risk processes. Similarly, child-specific factors (i.e., type of language difficulty, adaptive communication) likely moderate the relations between linguistic and behavioral difficulties, and determine whether – and to what extent – these difficulties are translated into more serious impairments. Specifically, children with higher levels of adaptive communication may be able to compensate for deficits in structural language skills and to minimize the effects of peer rejection and decreased opportunities for social–linguistic interactions. In addition, higher levels of receptive language skills likely permit more successful navigation of peer relationships (Craig, 1993). Thus, higher levels of these moderating processes (i.e., more responsive parent–child interactions, higher adaptive communication) are hypothesized to promote resilience, whereas lower levels of these processes are expected to confer risk for co- occurring language and behavioral difficulties. Furthermore, at least two potential mechanisms may underlie a transactional relation between language and behavior.

Pervasive, negative relationships with peers and adults are proposed to mediate the pathway from behavior problems to further language difficulties, whereas limited social–linguistic interactions are proposed to mediate the pathway from language difficulties to behavior problems. Given the observed heterogeneity in this population of comorbid children, specific factors likely influence which pathways children follow.

CONCLUSION

Given that language facilitates change in treating intra- and interpersonal conflicts, clinical assessment of adolescents referred for mental health treatment should include routine

evaluation of a range of language skills (Durkin & Conti-Ramsden, 2010). Moreover, numerous psychological interventions rely heavily on the individual's ability to use language to identify treatment goals, articulate the difficulties they are experiencing and exceptions to problems, reflect on their behavioral strengths and resources and regulate their own behavior and interactions. It should be remembered that psychoanalysis was described by Freud as the "talking cure".

When a language impairment is diagnosed, therapists must be apprised that there are areas rife with opportunities for miscommunications with some adolescents and where inaccurate inferences may be made about their behavior. Moreover, since there are therapeutic techniques for helping children and youth with higher order language impairments, failing to use such techniques is a serious gap in treatment that could be remedied (e.g., O'Donohue et al., 1999). As an example, overlooking higher order language impairment in adolescents is worrisome since this aspect of language is critical for written and spoken academic tasks as well as for social communication (Nippold, 2007; Conti-Ramsden et al., 2009). Therefore, measures of higher order language (and possibly of any aspect of language, considering both the expressive and receptive functions) should be included in future studies of children even younger than adolescence to determine how early such problems can be identified. Having made this recommendation, it is important to acknowledge that there is a paucity of standardized measures of higher order language with adequate sensitivity and specificity. Moreover, children's expressive language ability measured in a controlled testing situation may not correspond directly to their actual ability to communicate in everyday situations. Children's levels of 'adaptive communication' – which can be operationalized to denote 'real-world' usage of language to convey one's needs, feelings, and goals – may provide additional information about children's linguistic functioning that is not captured by standardized language testing scores. Several studies have demonstrated that behavior problems can be reduced through the provision of training in adaptive communication skills (for a review, see Mirenda, 1997). Adaptive communication may therefore be an important protective factor to include in a conceptual model of comorbidity, as higher levels may buffer the development of behavior problems among children with language difficulties.

To end with, it should be stressed that the connection between language and psychopathology seems to extend not only in childhood and adolescence, but also to adult age. This topic has been studied for instance in patients with schizophrenia, in whom an abnormal pathway to language development is considered by many authors to play a key role in the psychopathology of these patients (for review see Rapp & Steinhauser, 2013).

Chapter 5

**INTERCULTURAL NONVERBAL COMMUNICATION
COMPETENCE: MEETING BODY LANGUAGE
CHALLENGES IN FACILITATING AND WORKING
WITH STUDENTS FROM CULTURALLY DIVERSE
BACKGROUNDS IN THE AUSTRALIAN HIGHER
EDUCATION CONTEXT**

Ping Yang*

University of Western Sydney, Sydney, Australia

ABSTRACT

This chapter examines the role played by intercultural nonverbal communication competence of Australian university staff members working in a culturally diverse setting and its impact on the management of intercultural working relationships with the students. The discussion starts with a critical review of relevant nonverbal communication theories (e.g., paralinguistics, proxemics, and kinesics). Then it focuses on various body language challenges academic and professional staff members working in Australian universities face on a daily basis while facilitating and working with students who come from diverse linguistic and cultural backgrounds. The body language facing academic staff members inside classroom is challenging due to intricate intercultural differences and potential intercultural misunderstanding. It is argued that an issue common to both academic and professional staff members is that some of them may have insufficient intercultural nonverbal communication competence and few have received intercultural nonverbal communication training relevant to their work roles though their verbal communication skills are sound. It is believed that competent intercultural nonverbal communication is crucial and indispensable for both academic and professional staff members working in Australian university context because Australian higher education sector has such a linguistically and culturally diverse environment and it has an internationally high-stake profile with some

* Corresponding Author Email: p.yang@uws.edu.au

universities having as many as 20% or more international students from different cultures. This has created pedagogical implications that students are likely to achieve better learning outcomes and have better learning experience when their teachers are able to demonstrate their intercultural nonverbal communication competence. It is the same case with professional staff members whose competent intercultural nonverbal communication skills can accommodate students' various needs (e.g., psychological, emotional, and social). In a word, Australian university staff members' good intercultural understanding (language and cultural knowledge about international students, so-called clients) and effective nonverbal communication skills will contribute to presenting their universities a positive public image, internationalizing Australian higher education industry and making it competitive globally.

Keywords: Multicultural nonverbal communication, Australian universities, body language, paralinguistics, proxemics, kinesics

1. INTRODUCTION

Australia is one of the most popular destination countries to which more international students from the world over have been mobilizing for further education to expand their career opportunity. In Oct 2013, there were 502,328 international students¹ studying in Australia and in Oct 2014, the student number went up to 563,645. The top five countries from which 51.3% international students come from are China (150,521), India (59,138), Vietnam (28,992), South Korea (26,598), and Thailand (23,713). These countries are generally classified as belonging to collectivistic culture as opposed to individualistic culture which Australia comes under (Hofstede, 2001). People from collectivistic and individualistic cultures have contrasting cultural values which see them different from each other in verbal communication (e.g., making requests, using address terms) and nonverbal communication (e.g., having different concept of time and space, using different body languages). Because of such enormous cultural differences and such a high-stake international student population studying in Australian universities, it is essential that relevant stakeholders, particularly international students from collectivistic culture and Australian university academic and professional staff members have developed appropriate intercultural knowledge and nonverbal communication skills so that they can study and work in a healthy environment with their well-beings accommodated.

While Australian universities have ambitions to promote internationalization of Australian higher education, participate in international engagement and attract more international students for quality education and best learning experience possible (Barker & Mak, 2013), training in intercultural nonverbal communication competence needs to be provided to the frontline stakeholders (academic and professional staff, including management at all levels) so that they are willing to appreciate cultural diversities and approach intercultural differences positively. To discuss intercultural nonverbal communicative competence, the author will start with reviewing relevant literature in nonverbal communication theory with reference to intercultural communication context.

¹https://internationaleducation.gov.au/research/International-Student-Data/Documents/Monthly%20summaries%20of%20international%20student%20enrolment%20data%202014/10_October_2014_MonthlySummary.pdf.

Nonverbal communication covers paralinguistics (Crystal, 1971; La Barre, 1976), proxemics (Hall, 1966), and kinesics (Birdwhistell, 1970). Next comes the in-context discussion of various nonverbal communication challenges academic staff members (Neill & Caswell, 1993; Quinlisk, 2008) and professional staff members (Furnham & Petrova, 2010) working in Australian universities face on a daily basis while facilitating and working with students who come from diverse linguistic and cultural backgrounds.

Finally the chapter ends with a conclusion in which implications of intercultural nonverbal communication training in Australian higher education sector are discussed.

2. INTERCULTURAL NONVERBAL COMMUNICATION

Intercultural nonverbal communication sees people from different linguistic and cultural backgrounds interact with one another using their bodily resources readily available. It plays a fascinating role in that not only can people communicate a universally shared meaning but also negotiate context-embedded messages across cultural boundary. This requires participants in intercultural nonverbal communication to have appropriate intercultural knowledge and skills to make it happen. Research has shown that nonverbal communication, because of bodily attributes and practical use, is much more frequently employed than verbal communication in human interaction. It is interesting to consider the fact that we can choose to remain speechless but can hardly choose not to send messages nonverbally, even if unintentionally. For example, people have to display their facial expressions no matter whether they are happy or sad. It is essential to note the context in which intercultural nonverbal communication takes place can help explain the intended message. However, intercultural nonverbal communication can be complicated due to its multi-complex and multi-dimensional activities (Samovar, Porter, McDaniel, & Roy, 2013). These are reflected in the fact that intercultural nonverbal communication can be difficult and challenging unless participants are competent in intercultural communication and nonverbal communication. In this sense, it is meaningful to look at nonverbal communication in intercultural context. Although its dimensions can be explored in different ways (P. A. Andersen, Hecht, Hoobler, & Smallwood, 2003), nonverbal communication studies are broadly classified in this chapter into such categories as paralinguistics, kinesics and proxemics in the following discussion.

2.1. Paralinguistics

According to Crystal (1971) and La Barre (1976), paralinguistics covers such linguistic elements as tone of voice, volume of speech, speech rate, etc. and they each communicate meaning of a certain kind to the intended and unintended hearers. Kendall (2013) thinks that when people speak, their utterance will have a particular speech rate, pause, and some intervals of silence. They can be studied from a sociolinguistic perspective as to why one cultural group accepts longer silence time whereas another prefers to avoid it. A speaker's different tone of voice is found to have different impact on the listeners' memory of texts (Helfrich & Weidenbecher, 2011). Specifically they find that both high and low tones of voice tend to help retain longer memory of text content than medium tone of voice. Caucci

and Kreuz (2012) claim that a speaker can convey a sarcastic message through a specially designed tone of voice in a particular situation. Intercultural communicators need to take special care to become aware of cultural sensitivity so that they avoid using any tone of voice that may sound arrogant or ironic to the other party.

Appropriate volume of speech is important for the intended audience to hear the message and whether loudness is appropriate or not may be interpreted differently across cultures. Volume of speech appropriate to a large audience in a lecture hall may be considered too high for a small group people in a lounge. Crookes (2003, p. 72) discusses the relevant intercultural communication challenges teachers face as follows.

We expect speech to have a volume appropriate to mutual interpersonal distance, as culturally defined, for example; and when such expectations are not met – when, for example, what we interpret as “shouting” takes place at close range, or when whispering takes place at a distance – the strict content intended by the words alone may be overridden by the implication drawn by the listeners as to what the speaker really means by behaving in this unusual way.

The above complex issue is made more challenging in intercultural interaction, frustrating not only teachers in the classroom setting, but also parties engaged in everyday social interaction. Although negative stereotyping is to be avoided, there is an issue among some Black American high school students so that a set of values had to impose on student behavior school administrator considered “underclass” and “particularly stigmatized was “loud” behavior, which not only marked the individual as “underclass” but also was viewed as dishonor to the race” (Cole & Omari, 2003, p. 788). Voice volume considered normal in one context could be regarded as inappropriate in another. In March 2014, Mrs. Marian Robinson², President Obama’s month-in-law, was allegedly reported to be “barking at the staff since she arrived” at Beijing Westin Hotel with her daughter Michelle Obama and her two granddaughters. Similarly, some of Chinese tourists were criticized for their irritating habits, including “talking loudly in public, jaywalking, spitting, and carving characters on items in scenic zones³.” As people travel more to other countries, they have a better chance, when having some pre-departure briefing sessions, to increase their intercultural awareness and understand cultural differences through observing, interacting, and reflecting.

There is a relationship between speech rate and listening comprehension and it is generally believed that listening comprehension decreases as speech rate increases (Griffiths, 1992). This is particularly the case with learning a foreign or second language which may have different phonetic, lexical, or syntactic systems from the learner’s first language (L1). For example, English and Chinese belong to two different language families, with the former being from the Indo-European family and the latter being from the Sino-Tibetan family (Akmajian & Demers, 2010; Campbell, 2013). Because their phonetic, lexical, or syntactic systems differ and there are socio-cultural and pragmatic differences between the two

² Martosko, D. (2014). Beijing hotel workers already ‘fed up’ with Obama entourage in 3400-square-foot, \$8,350-per-night suite inconveniencing ‘pretty much everyone’ — and the first lady’s mother is ‘barking at the staff’. *Daily Mail*. 23 March 2014. languages, faster speech rate can considerably affect Chinese/English speakers' listening comprehension of English/Chinese as a second language (L2).

2.2. Kinesics

Kinesics (Birdwhistell, 1970) has a focus on studies of a wide range of body-related cues, such as facial expressions, eye contact, head movement, gesture, and body ornaments. Body language researchers' kinesics projects and research outcomes are colorful. It is claimed that facial expressions are universally similar, but Ekman and Friesen (2003) question whether people from different cultural backgrounds share the same facial expressions. Relying on laboratory-based experiment results, Ekman (2006, p. 24) demonstrates that "the Japanese masked their facial expressions of unpleasant feelings more than did the Americans", thus concluding that Japanese speakers display their facial expression emotions differently from those displayed by American speakers. Furthermore, he believes that there is more than one "surprise" facial expression. Similarly, Yang (2013b, pp. 108-110) explains there are different kinds of "smiling" emotions and varied implications in Chinese, with some of them being complimentary (e.g., *wēixiào*, 微笑, a gentle smile with emotional displays of warmth, gentleness and friendliness) and others being derogatory (e.g., *jiǎnxiào*, 奸笑, a sinister smile with emotional displays of villainess). As people from different cultures input unique cultural meaning into their facial expressions, apparently there is a need to consider the cultural uniqueness of these emotions when they are displayed in given cultural contexts.

As for eye contact, one study reports that American blacks use less speaker-directed gaze than their white counterparts (Greenbaum & Greenbaum, 1983). Maintaining eye contact is essential in English communication and all parties are expected to maintain appropriate eye contact while engaged in talk-in-interaction. However, things are more complicated in Asian communication context where high social power distance (e.g., teacher-student) has impact on interpersonal relationship. Head movement is characterized by heading nodding for 'yes' and heading shaking for 'no'. But there are also exceptions in India where Indian⁴ speakers wobble their head for 'yes'. This sends a head shaking with 'no' to speakers from most cultures. What is most striking about Bulgarian⁵ head movement is that Bulgarian speakers nod their head for 'no' and shake their head for 'yes'. McNeill (2005, p. 38) groups gestures into four categories: "iconic, metaphoric, deictic and beat" and explains their definitions. While iconic gesture is indicative of a concrete image or picture being described, metaphoric gesture is symbolic of an abstract thing or idea under discussion. They can be a head, finger or hand gesture of various kinds. Deictic gesture is generally used to point to a certain direction or a thing in the form of a finger. It can also be executed in the form of a lip-pointing used by Laos speakers (Enfield, 2001), a chin-up-pointing used by Chinese speakers (Yang, 2010, 2013b). Other hand gestures can send many culture-loaded messages. For examples, Cantonese⁶ speakers tap their finger tips on the table for thanking when being served some food or tea in a Chinese restaurant (Yang, 2013b). Beats are "mere flicks of the hand(s) up and down or back and forth that seem to 'beat' time along with the rhythm of

⁶ http://www.youtube.com/watch?v=47ng8jkK_CA.

speech” (McNeill, 2005, p. 40). Gestures can be very colorful, expressive and diverse with some shared by different cultures and others being culture-specific.

Body ornaments are used by people from diverse cultural backgrounds around the world to represent their unique cultural traits and make them different from those from other cultures. These cultural phenomena can be studied through examining different color ornaments and object ornaments, which carry specific cultural and psychological meanings. Chromatics is about how significantly colors are valued in a given cultural group (Hurn & Tomalin, 2013). At a wedding party, a traditional Chinese bride wears a red wedding dress⁷ while an English counterpart wears a white wedding gown⁸. At a funeral ceremony, mourners wear black or dark-colored suits in most Western countries (e.g., the UK, Australia and the US) whereas most mourners wear white clothes (it could vary with the occasions; people wear black with a white flower and/or a black armband at a state funeral.) or dark-colored ones in many Asian countries (e.g., China, Japan) (Hurn & Tomalin, 2013; Leach, 1958). Objects are often used to decorate human bodies and outlook in various ways so that they appear smart, fashionable and culturally identifiable in public places. One of the significant reasons is cultural identity. As Seeger (1975) indicates, body ornaments should be studied with reference to their cultural context, thus bringing to light their culturally unique meaning. Nonverbal communication can take on a very impressive, striking, and new mode and look more multimodal and multifunctional, when it occurs in intercultural context.

2.3. Proxemics

The term proxemics is created by Hall (1963) and it refers to the study of how interpersonal distance and space is maintained between people from the same or different cultural backgrounds. Nonverbal immediacy is used to describe a range of nonverbal cues, such as proxemic closeness (e.g., space), bodily closeness (e.g., touch), kinesic cues (e.g., eye contact, gaze and smiles), vocal expressiveness and informal dress communicators depend on to achieve affective and relational communication while engaged in interaction (J. F. Andersen, Andersen, & Jensen, 1979). Hall (1966) views personal space as a dimension constantly hidden in intercultural communication, but meaningful as its research can help understand why intercultural misunderstanding occurs due to different space management and how people can communicate effectively across cultures with consideration and awareness of others’ space. While smaller interpersonal distance and space is kept among members of collectivistic culture, greater interpersonal distance and space is maintained among members of individualistic culture. For example, interpersonal space considered culturally appropriate by European Americans may be regarded as distant by Arabs whereas interpersonal space considered culturally appropriate by Arabs may be regarded as close by Northern Americans (Ting-Toomey, 1999).

Furthermore, gender has a role to play in people’s dealing with space and distance in intercultural communication settings. Whereas people generally do not socially accept the practice that the same-sex persons live in one room in some cultures, the same practice is

⁷ <http://www.youtube.com/watch?v=SxPcXfjNzKY> (It is noted that some young lovers living in the cities in China have chosen to have their wedding ceremony in the Western fashion with the bride wearing white wedding gown.)

⁸ <http://www.youtube.com/watch?v=OLTg1WOKqC0>.

regarded socially acceptable in others. For example, it has been common in many Asian countries that non-gays or non-lesbians adult students share a university dormitory because of limited room resources. Another example to explain gender role and social distance is about Saudi women who do not stay close to men due to social norm and religious practice in Saudi Arabia (Hamdan, 2005). Additionally, Saudi women are expected not to shake hands with men and keep appropriate distance from them in public for the same reason. Gender role is defined in the cultural and religious practices which are worth consideration in studying multicultural nonverbal communication.

3. UNDERSTANDING AND MEETING MULTICULTURAL NONVERBAL COMMUNICATION CHALLENGES IN AUSTRALIAN HIGHER EDUCATION SETTING

Most international students studying at Australian universities come from Asian countries which have become the center stage of the world. Their home countries are typical of collectivism in contrast to individualism which is characteristic of Australia. Collectivism is characterized by its group conformity, indirect communication, nonverbal cues while individualism is highlighted by its individual-centeredness, direct communication and verbal utterances (Gudykunst, 1997; Hofstede, 1980; Scollon, Scollon, & Jones, 2012; Triandis, 1990). Such culturally defined features explain why people belonging to collectivistic culture or individualistic culture communicate and behave in different ways. Simply because there are such contrasting differences between collectivistic culture and individualistic culture, cross-cultural misunderstanding is likely to occur when people from these cultures interact with each other. As classrooms in the West are mostly multi-ethnic and inter-ethnic, understanding ethnic communication, including its multicultural nonverbal communication patterns, comes into play and meanwhile challenges, such as “inferior-superior dichotomy” (Edward T. Hall & Hall, 1986, p. 364) and asymmetrical style of nonverbal communication (Yang, 2013a), for classroom teachers emerge. Intercultural nonverbal communication may add to misunderstanding due to its implicitness, high-context and culture-binding. Although many of their cultural differences between the East and the West have been identified and investigated (Brown, 2009; Jackson, 2014; Martin & Nakayama, 2014; Samovar et al., 2013; Scollon et al., 2012), comparatively insufficient work has been done about intercultural nonverbal communication between teachers and students coming from different language and cultural backgrounds. In this chapter, focus will be placed on intercultural nonverbal communication differences in Australian universities which are characterized by multilingual and multicultural profiles.

3.1. Accommodating Students’ Learning Needs As Words Only May Fail to Communicate

Classroom communication is essential in that the teacher is facilitating the students in acquiring various skills and learning knowledge and such guidance is implemented through verbal and nonverbal communication. Although verbal communication in the classroom

context is actioned through teacher talk, its nonverbal cues are embedded and paralinguistic features are projected through speech rate, volume, and tone of voice. It is important to note that they not only convey some unintended meaning, but may also have positive or negative impact on the students. For example, nonverbal communication can work to attract students' attention and help them learn and become motivated to learn more, on the one hand, and it may make them bored and lose attention if not well managed on the other.

One of the issues lies in the speech rate used in the classroom. A teacher's speech rate needs to accommodate newly arrived international students' receptive abilities and guide them with a purpose so that they are encouraged to follow. The teacher needs to be aware that failure to follow the fast talker can occur because English as second language (ESL) students may initially be in the habit of mentally translating received information or have difficulty understanding some culture-loaded words or slangs in the talk. Furthermore, students sitting at the back of the lecture theatre may not hear if a teacher talks at a low volume and it seems that weak students tend to choose to sit there. As far as tone of voice is concerned, Helfrich and Weidenbecher (2011) find in their experiment that speakers using low-pitched voices are more favored than those using high-pitched voices, and that long-term memory is facilitated better by both high- and low-pitched voices than by medium-pitched voices. While monitoring their student learning process and progress, an experienced teacher always keeps alert and is ready to adjust their speech rate, volume of voice and tone of voice dynamically and flexibly to facilitate student learning.

3.2. Body Language Speaks Louder Than Words

One of the commonly misunderstood phenomena is that teacher-student verbal interaction in Australian classroom context naturally leads to communication and student learning so long as a teacher speaks English fluently. Such misunderstanding apparently ignores two basic facts. First, it fails to recognize the role body language plays in the classroom communication. Classroom teaching is more than a two-way talk activity only because body language speaks louder than words and its appropriate and purpose-built application adds to meaningful interaction (Harmer, 2007). Successful classroom communication involves not only a flexible use of easy-to-understand language expressions but also an empathetic understanding and effective use of body language for pedagogical purpose and for intercultural communication.

Body language (e.g., iconic, metaphoric, and deictic gestures) conveys thoughts and meanings, and effectively supports and explains verbal communication as classroom instructions, thus helping students understand learning tasks. When returning to McNeill's (2005) iconic gesture, we find using this body language presents a vivid image of the object under discussion and builds connection between shape and size and semantic meaning intended. Researchers conducting experiments on the relationships between speech and accompanying iconic gesture find that there is a high correlation in communication between the two (Beattie & Shovelton, 2001). For example, the teacher describes the differences between the shape of tropical fruits 'lychee' and 'rambutan', using an iconic hand gesture to map out a round shape for the former and an oval shape for the latter while pointing to the images projected on the screen. The iconic gesture is effectively used to highlight one of the important physical features of the two fruits being discussed, thus giving students a good

impression on how to recognize their important difference. As another example, White and Gardner (2012) describe how classroom teachers can create X-factor in the classroom environment through using effective nonverbal communication and maximize student learning experience by applying teaching methods supported by psychology and cognitive science.

Body language conveys emotions that help build teacher-student rapport and mutual trust. University teachers' enthusiasm in the profession may be reflected in their facilitating hand gesture and encouraging eye contact which can help inspire and stimulate student motivation to learn more cooperatively. Emotion and body language work to appeal to the students' attention and engagement in the topic discussion. For example, when explaining Adult Migrant English Program (AMEP), the teacher, using an open and warm embracing hand gesture, talks about how to accommodate the psychological and cross-cultural adaptation needs of refugee learners by creating a welcoming classroom environment (e.g., team them up with fellow students who speak the same L1). The class is also reminded that refugees are treated equally in Australia and some of them have skills in different trades (e.g., plumbers, carpenters and mechanical engineers, etc.) although others remain even illiterate in their home language due to wars and trauma experience (Benseman, 2014). The class is filled with a positive atmosphere of interpersonal emotion and cross-cultural understanding which increases students' confidence and trust in the teacher and their philosophy through verbal messages and nonverbal cues in particular. For another example, teachers use encouraging eye contact to motivate adult L2 learners to be willing to participate and communicate (Brown, 2007). Understanding the adult learners' potential capabilities, teachers guide them to use their analytical skills and mobilize them to contrast and analyze differences between their home language and English. Meanwhile they encourage them to engage in task-based learning and pair/group discussion by using warm and trusting facial expressions. Furthermore, students' use of gesture, gaze, body orientation for collaboration and socialization with their fellow students is related to task performance and effective communication in context (Platt & Brocks, 2008).

Second, it is important for Australian university staff members, particularly classroom teachers, to become aware of and literate about various multicultural differences in nonverbal communication when they interact with international students because their body languages are connected with their own cultural values and social or religious practices. Even if teachers may insist on what is normally accepted in an Australian classroom where students have diverse cultural backgrounds (Crookes, 2003, p. 75), they most often find it helpful to build and maintain teacher-student rapport when they show genuine interest in individual student's language and culture and recognize their cultural experiences using appropriate body language. As many Australian universities are working to promote international engagement and internationalization of Australian education industry, their staff members find it beneficial to become aware of multicultural nonverbal communication styles and patterns. Although eye contact is important in English communication, they need to know students from other cultural backgrounds may not maintain eye contact as expected due to different cultural perception (e.g., high power distance between people of different age and status may affect talk turns of those from collectivistic culture) (Greenbaum & Greenbaum, 1983; Yang, 2013a). In beckoning international students (e.g., from China and the Philippines), Australian teachers need to avoid using a single-upright-finger beckoning (e.g., used when beckoning a dog in China and the Philippines) simply because it is an insulting gesture in Chinese and

Filipino cultures. Silence among L2 learners is very common and normal particularly when they are new in Australia and may need to adapt, due to cultural shock and anxiety, to the host learning environment which differs much from their previous one. Individualistic culture focuses on verbal communication and English-speaking academics tend to view international student silence negatively as keeping silent is generally less acceptable in English speaking world (Martin & Nakayama, 2014). Additionally, there are cultural differences between Australian mainstream society and Australian Aboriginal communities. It is found that different Australian ethnic groups have different response to silence as a social practice. Mushin and Gardner (2009) report that Australian Aboriginal speakers observe longer silence in conversation which is socially accepted Aboriginal communities whereas it is avoided among Anglo-Saxon Australians and is not practiced in the white communities. It would be a friendly reminder for Australian university staff members to be aware of such ‘sociolinguistic interference’ which is to be approached positively and flexibly as part of multicultural nonverbal communicative competence (e.g., cultural knowledge and social skills). So it is the case with international students coming from different language and cultural backgrounds. To practice ‘student-centered’ philosophy, Australian universities need to provide their staff members with intercultural nonverbal communication training as part of professional development and enhance their intercultural nonverbal communication competence. Intercultural nonverbal communication is more effective and beneficial when teachers and students are aware of its differences and able to adapt to them.

3.3. Nonverbal Immediacy: Dos and Don’ts

Nonverbal immediacy is defined as speechless behaviors or actions that are performed to narrow social, physical, or psychological distance or space between people engaged in interaction (Malachowski & Martin, 2011; Richmond, 2002). It is characterized by integrating paralinguistic cues (e.g., warm vocal cues), proxemic cues (e.g., bodily closeness) and kinesic cues (facial expressions like smiling) all in one. Such nonverbal complex comprises multidimensional bodily cues that work together to achieve communication purpose (Samovar et al., 2013; Yang, 2013b). Although nonverbal immediacy is generally positive and intended as such in university setting, it needs to be practiced carefully and with discretion. It is important for Australian university staff members to see the specific situation in which it is applied with reference to different cultural practices and keep in mind the multicultural differences of nonverbal communication.

Researchers are confident that if teachers use nonverbal immediacy appropriately it is conducive to effective communication and motivation, thus having positive impact on students’ affective learning (Plax, Kearney, McCroskey, & Richmond, 1986; Witt, Wheelless, & Allen, 2004) and on effective teaching outcomes (Özmen, 2011). For example, research outcomes show that teachers’ nonverbal immediacy in the classroom interaction contributes to their students’ willingness to communicate and better learning outcomes (Yu, 2011). If teacher-student rapport is developed and maintained with the help of nonverbal immediacy, teachers and students are more likely to have genuine interest and trust in each other. When this occurs, both parties will find collaborative teaching and learning process effective and enjoyable.

Despite its advantages, increased teacher immediacy may cause some potential issues to emerge. It is helpful to know that some of nonverbal behaviors should be avoided due to cultural differences in nonverbal communication. First, male teachers should make efforts to avoid using excessive nonverbal immediacy. It is noted that female and male teachers' excessive use of nonverbal immediacy are rated differently. While the former group's behavior tends to be rated positively, the latter group's behavior is rated negatively (Rester & Edwards, 2007). Second, it is culturally sensitive for male teachers to prevent themselves from having body contact, for instance, a hand shake or a cheek kiss, with Arabic-speaking females due to their religious practice. However, Arabic-speaking males usually keep less space with their friends of the same sex and tend to touch them more often than do those from the Western countries, and they may also be "close to or touching strangers" (Nydell, 2012, p. 26). Third, people from the East and the West have different sense of public and private space. What seems to be appropriate social distance to Arabs is somewhat too intimate for Westerners. Nydell (2012) also reports that there is nothing strange for Arabic speakers of the same sex to walk on the street hand in hand in the Arab world. While this is an indication of friendship and solidarity in Arabic culture, it is very uncommon in English society, except that the same-sex parties are homosexual partners. Similarly, it is common for several students of same sex to share one dormitory on Chinese university campuses whereas it is very rare for students of the same sex to do so on Australian university campuses. Apparently, nonverbal immediacy is viewed and managed differently and social practices in bodily proximity vary from culture and culture.

CONCLUSION

This chapter centers on the important role intercultural nonverbal communication plays in teacher-student classroom communication in multicultural Australian university context. With the white paper *Australia in the Asian Century* issued in 2012, Australia has been part of the great Pacific Rim and has strengthened its economic and diplomatic link with Asia as the center of the globe. Meanwhile, Australia's international education has been highly rated and has become a good example for some European universities to follow (Adams, 2007). In addition, Australia has remained one of the English-speaking destination countries where international students seek to further their higher education. Most of these young people come from Asian countries which are typical of collectivism in contrast to individualism which underlies the cultural values of Australian mainstream society. Such difference in cultural values highlights the orientation that members of collectivistic culture prefer indirect and nonverbal communication style in high context as opposed to direct and verbal communication style in low context practiced by members of individualistic culture.

While the above cultural diversity is beneficial in that it opens a wider window for members of the two broadly categorized cultures, it tests both parties' capacity to appreciate something different from their own culture. Intercultural nonverbal communication styles projected from different cultural values pose challenges to both Australian university staff members and international student cohorts. For Australia's international education to maintain sustainable development and growth, Australian universities would place themselves in a more competitive and advantageous position and would be more likely to succeed in

international education business if they provide their staff members with relevant intercultural communication training, including nonverbal communication skills (Chaney, 2014; Furnham & Petrova, 2010; Waistell, 2011). Furthermore, Australian university staff members and international students may find it beneficial to develop their intercultural knowledge and nonverbal interpersonal communication skills so that they can become broad-minded and understand each other better, hence building and maintaining sound teacher-student working relationships. This can make it possible for teachers to work more efficiently and to the best of their ability, showing interest in assisting each individual student with their learning needs. At the same time, international students need to make great efforts to work diligently and consciously, and to achieve the expected learning outcomes of university coursework or to complete planned higher degree research projects, making a good use of limited time to score maximum achievements, and achieving intercultural adaptation to Australian university environment and social life.

Intercultural nonverbal communication is a two-way ticket taking Australian universities, their staff members, and students, both international and domestic, to an upper level of win-win success. Classroom communication and student learning are enhanced and facilitated through teachers' effective use of nonverbal communication aided by a good understanding and intercultural awareness (Neill & Caswell, 1993; Quinlisk, 2008). As the English language is becoming a lingua franca, so are intercultural nonverbal communication styles and patterns, which requires Australian higher education practitioners to reflect on a new concept of intercultural nonverbal communication, that is integration of Australia' nonverbal communication style and pattern with those of international students', similar to what Alptekin (2002) argues in favor of intercultural communication competence in English language teaching. Facial expressions, like a smiling face, are a starting point where East meets West with mutual interest in knowing and understanding the others' languages and cultures. More Australian university members have friendly smiling photos on their staff profiles than their counterparts in the non-English background nations, but it is in the specific classroom and social interaction context that their intercultural nonverbal communication competence is put to test.

Chapter 6

PHONE DURATION MODELING OF THE SERBIAN LANGUAGE: COMPARATIVE EVALUATION OF DIFFERENT MODELS

Sandra Sovilj-Nikić* and Ivan Sovilj-Nikić

Faculty of Technical Sciences, University of Novi Sad, Novi Sad, Serbia

ABSTRACT

Having in mind the importance of segmental duration from a perceptive point of view, a specialized module for modeling segmental duration in natural speech is a very important component of a text-to-speech (TTS) system in order to produce high quality synthetic speech which sounds natural. In this study various machine learning techniques were applied for phone duration modeling of the Serbian language. In this chapter different phone duration prediction models for the Serbian language using linear regression, tree-based algorithms and meta-learning algorithms such as additive regression, bagging and stacking algorithm are presented. Phone duration models have been developed for the full phoneme set of the Serbian language as well as for vowels and consonants separately. A large speech corpus and a feature set of 21 parameters describing phones and their contexts were used for the prediction of segmental duration. Phone duration modeling is based on attributes such as the current segment identity, preceding and following segment types, manner of articulation (for consonants) and voicing of neighboring phones, lexical stress, part-of-speech, word length, the position of the segment in the syllable, the position of the syllable in a word, the position of a word in a phrase, phrase break level, etc. These features have been extracted from the large speech database for the Serbian language. The phone duration model obtained using additive regression method outperformed the other models developed for the Serbian language within this study using different modeling techniques. This model obtained for the full phoneme set outperforms the second best model by approximately 1.3% and 1% in terms of the relative reduction of the root-mean-squared error and the mean absolute error, respectively.

1. INTRODUCTION

In natural speech the duration of speech segments depends on the context of speech, where that dependence is very complex and involves many factors [1]. The study of speech timing and impact of different phonological, syntactic, physiological and other factors on the duration of speech segments is very important for both understanding the process of speech production and the development of speech synthesis in order to produce high quality synthetic speech [2], [3]. Therefore, a very important component of a text-to-speech (TTS) system is a specialized module (duration system) whose task is modeling segmental duration in natural speech, taking into account various factors. Identifying the most influential factors is a crucial step in the duration modeling process because selecting inadequate or incomplete sets of factors can lead to large errors of duration prediction. Having in mind the nature of the problem, a set of factors that describe the context of speech is composed of only those features that could be extracted from the text. The importance and effect of certain factors on the duration are directly correlated with a particular language and the sets of influential attributes vary considerably in different languages. The choice of this set requires a high level of linguistic information, as well as a statistical analysis of speech corpora in order to determine the accurate value of phone duration in a given language, having in mind the importance of the duration of speech segments from the perceptual point of view [4], [5].

Models for predicting the duration can be divided into two groups: rule-based models and corpus-based models. One of the most well known models for predicting duration using rules, and the oldest one, was developed by Dennis Klatt [1]. In this type of model, there is an assumption that each phoneme has an intrinsic duration which is inherently one of the distinctive features of phonemes. The intrinsic duration is assigned to a given segment and it is then modified by applying successive rules. In this type of duration system an occurrence of exceptions usually represents a problem because the rules are such that they most often lead to over-generalization. The main advantage of such models is that they do not require large speech corpora, which was of great importance at the time of their creation, when computational resources needed for generating and analyzing large speech corpora were not available as today.

However, by the development of computer technology, corpus-based models are becoming more prevalent. Corpus-based statistical models require a large speech corpus because the modeling is done using a machine learning algorithm on large speech corpora. Depending on machine learning approach applied for phone duration modeling, van Santen [5] distinguishes three types of models:

- linear statistical models,
- models obtained using a neural network and
- models based on decision trees.

The first such model for predicting the duration of speech segments in American English was developed by Riley [6] using the CART (Classification and Regression Trees) technique. The technique developed as a combination of statistics and artificial intelligence has many advantages and as such today represents one of the most commonly used methods for modeling the duration of speech segments. One of the main advantages of the CART method

is the ability to find out structural relationships between the predicted and actual values [7]. This is the reason why the CART method is commonly used in the initial stages of phone duration modeling research. The application of this method for modeling phone duration in different languages has given sufficiently good results. Phone duration modeling using the CART method has been implemented for many languages, including Czech [8], Greek [9]-[11], Lithuanian [12], Mandarin, British English, Vietnamese, Serbo-Croatian [13], Serbian [14], Korean [15], Turkish [16], and Indian languages Hindi and Telugu [17].

In addition to phone duration models based on decision trees, various machine learning approaches have been applied for modeling phone duration in different languages such as artificial neural networks [18], [19], sum of products models [2], Bayesian networks [20], and instance-based algorithms [21].

In this chapter the authors present different phone duration prediction models developed for the Serbian language using linear regression, tree-based algorithms and meta-learning algorithms such as additive regression, bagging and stacking algorithm. The performances of these models are evaluated by objective measures such as root-mean-squared error (RMSE), mean absolute error (MAE) and correlation coefficient (CC). The comparative evaluation of different models developed for the Serbian language is also performed. The results obtained for the full phoneme set of the Serbian language as well as for vowels and consonants are shown and discussed.

In the Introduction the authors present an overview of different approaches to duration modeling, emphasizing in particular the significance of phone duration modeling in speech synthesis. Section II gives the description of the speech database used for extracting a feature set and modeling phone duration as well as a detailed description of the feature set for the Serbian language. Phone duration modeling process using different algorithms is described in Section III. In Section IV experimental results are shown and discussed. Finally, conclusions and further research directions are given in Section V.

2. FEATURE SET FOR THE SERBIAN LANGUAGE

In the duration modeling process a necessary component of a TTS system, which precedes the module for predicting the duration of a speech segment in a given context, is a module that automatically generates the appropriate feature vector that represents each phoneme in the speech database. The elements of the vector describe the characteristics of the speech segment and the context in which it is located, where the value of each feature is actually one of the possible levels of the factors that influence the duration of the speech segment.

If the speech segment in the database is represented by the corresponding feature vector f , and if factor f_j indicates the presence of lexical accent in a syllable and it takes one of mutually exclusive values from the set {stressed, unstressed}, then the feature vector element has one of the possible values of the factor f_j . The space of all factors product $f_1 \times f_2 \times \dots \times f_n$ is called the feature space $\mathbf{F}$. However, due to the different phonological and other linguistic limitations, not all combinations of different factor values are allowed in any language. Therefore, the linguistic space is defined only by the feature vectors that really

occur in a particular language. It is significantly smaller than the feature space and it represents a subset of feature space. On the other hand, the number of possible linguistic combinations of different factor values in any language is extremely large and the recording of such a speech corpus exceeds reasonable time limitations [2]. Thus, when selecting material for speech database recording a lot of attention is focused on finding material that will contain as many different potential linguistic combinations as possible, in order to achieve the highest possible coverage of linguistic space. Despite all the efforts, the speech corpus is often only a small subset of linguistic space [22].

The factors which will be taken into account when developing a model of phone duration in speech synthesis in the Serbian language were selected on the basis of the most influential factors that different authors used for phone duration modeling in different languages [1], [8]-[17] and on the basis of previous studies concerning the effect of various factors on the duration of phonemes in the Serbian language [23], [24]. All the factors, which will be mentioned later, have been extracted from the speech database in the Serbian language, recorded for the needs of the existing speech synthesizer [25]. The aforementioned corpus used in this paper contains approximately 2000 sentences and 16000 words, and the majority of its contents are texts from the daily press, which are typically used for such purposes. The speech database was recorded in a sound proof studio and the voice of a female professional radio announcer was employed. She is a native speaker of Serbian, who speaks the Ekavian standard dialect. The recorded speech was sampled at 88.2 kHz. The recorded material was annotated phonetically and prosodically. The AlfaNumASR speech recognition system [26] was used for temporal alignment on the phonetic level and the correction of phone labels was carried out manually using the AlfaNum TTSTLabel software [26]. The prosodic annotation involved marking lexical stress (four stress types and post-accentual length), sentence focus and phrase break levels. The prosodic annotation was conducted manually using the AlfaNum TTSTLabel software [26].

Each phoneme in the speech database is presented using the appropriate feature vector which describes the given speech segment and the context in which the phoneme occurs. In addition, the relevant factors and their potential values in the Serbian language are given. The factors are classified according to the domain of their impact.

• Nature of the segment

segment identity: It can be one of 43 different values, including the five vowels in the Serbian language, two different realizations of schwa /ə/ and 25 consonants. Since stops and affricates are labeled in the database as pairs of semi-phonemes that consist of occlusions and explosions in the case of stops and of occlusions and frictions in the case of affricates, the total number of different consonants is therefore 36. Distinction is made between two different types of the semi-phone /ə/ - one that accompanies the phoneme /r/ in consonant environments, and the other in its syllabic use [27]. If used as a syllabic consonant, phoneme /r/ may be a syllable nucleus and that realization of the vocalic element /ə/ should differ from that in which /r/ is not the nucleus of a syllable.

segment type: vowel, consonant

manner of articulation (for consonants): stop, fricative, affricate, nasal, lateral, semivowel, trill

place of articulation (for consonants): bilabial, labio-dental, dental, postdental, alveolar, palatal, velar

- **Neighboring segments**

segment type: vowel, consonant, silence

manner of articulation (for consonants): stop, fricative, affricate, nasal, lateral, semivowel, trill

voicing: voiced, voiceless

Place of articulation of the preceding and following consonant is not considered because previous studies have shown that it is not a relevant factor [28].

- **Position of segment in syllable**

syllable initial: yes, no

position in a syllable: onset, nucleus, coda

- **Syllable**

lexical stress: stressed, unstressed

stress type: short-fall, long-fall, short-rise, long-rise, post-accentual length

- **Position of syllable in word**

word initial: yes, no

word final: yes, no

- **Word**

part of speech:

– inflected words: noun, verb, adjective, pronoun, number

– indeclinable words: preposition, adverb, conjunction, particle, exclamation

word length: the number of syllables in the phonological word

- **Focus**

focus: particularly highlighted word, relatively unimportant word, neutral word

- **Position of word in phrase**

break level: no break, weak break, medium break, strong break, hesitation break, sentence end break

The different break levels correspond to different perceptually detected breaks, in the cases where the break coincides with the interval of silence, it is possible to distinguish between initial, medial and final position of a word in the phrase.

3. PHONE DURATION MODELING USING MACHINE LEARNING ALGORITHMS

In the process of phone duration modeling of the Serbian language various machine learning techniques were used including linear regression, tree-based methods and meta-learning algorithms such as additive regression, bagging and stacking algorithm. In the following a brief description of the above mentioned methods is given.

Linear regression [29] is one of the methods used for the prediction of numerical values. This very simple method is also the oldest method of regression analysis. It has been extensively studied for many years and it is extensively used in many practical applications. The basic idea of this algorithm is that the dependent variable or predictive value is to be presented as a linear combination of attributes which will be taken into account when forming a predictive model and upon which the predictive value depends. Each of the attributes is weighted by the appropriate weighting factor.

Therefore, the dependent variable can be written as:

$$x = w_0 + w_1 a_1 + w_2 a_2 + \dots + w_k a_k \quad (1)$$

where: x is the predictive value or the phone duration in the case of duration modeling

$a_1, a_2, \dots, a_k$ are the factors affecting the duration of phonemes

$w_0, w_1, \dots, w_k$ are weighting factors

The weighting factors are determined based on the training data, which are in the speech database.

The predicted value of the duration for the first phoneme in the database can be written as:

$$x = w_0 a_0^{(1)} + w_1 a_1^{(1)} + w_2 a_2^{(1)} + \dots + w_k a_k^{(1)} = \sum_{j=0}^k w_j a_j^{(1)} \quad (2)$$

In determining the coefficients w_j , there are $k+1$ of them, the method of the least squares is applied, and it is necessary to minimize the sum of squares of the differences between the actual and the predicted values over all the training data.

If there are n phones in the database, wherein the i -th phoneme denoted with superscript (i) then the sum of the squares of the differences can be represented as:

$$\sum_{i=1}^n (x^{(i)} - \sum_{j=0}^k w_j a_j^{(i)})^2 \quad (3)$$

where the difference in parenthesis is the difference between the actual and the predicted value of the duration of the i -th phoneme in the database. By choosing appropriate coefficients w_j the sum of squares is minimized.

CART method [7], developed as a combination of statistics and artificial intelligence, has a number of advantages and, as such, today is one of the most commonly used methods for modeling the duration of speech segments. Modeling speech segments duration using the CART technique involves the use of a regression tree for predicting the duration of a given

speech segment which is in the database represented by a corresponding feature vector. The formation of the tree consists of several steps: the formation of the question set and selection of the best question for splitting in the given node; selection of stopping criterion in a node, or declaration of a given node as a terminal node (leaf); prediction of a value in a given node.

The most popular splitting criterion is the mean squared error. Suppose Y is the actual duration for training data X , and then the overall prediction error for a node t can be defined as:

$$E(t) = \sum_{\mathbf{X} \in t} |Y - d(\mathbf{X})|^2 \quad (4)$$

where $d(\mathbf{X})$ is the predictive value of Y .

The next step is the selection of the best question which is equivalent to finding the best split for the instances of the node. We should find the question with the largest squared error reduction or the question q^* that maximizes:

$$\Delta E_q(t) = E(t) - (E(l) + E(r)) \quad (5)$$

where l and r are the leaves of the node t . We define the expected square error $V(t)$ for a node t as the overall regression error divided by the total number of instances in the node:

$$V(t) = E \left(\sum_{\mathbf{X} \in t} |Y - d(\mathbf{X})|^2 \right) = \frac{1}{N(t)} \sum_{\mathbf{X} \in t} |Y - d(\mathbf{X})|^2 \quad (6)$$

One can notice that $V(t)$ is actually the variance estimate of the duration if $d(\mathbf{X})$ is made to be the average duration of instances in the node. With $V(t)$, we can define the weighted squared error $\bar{V}(t)$ for a node t as follows:

$$\bar{V}(t) = V(t)P(t) = \left(\frac{1}{N(t)} \sum_{\mathbf{X} \in t} |Y - d(\mathbf{X})|^2 \right) P(t) \quad (7)$$

Finally, the splitting criterion can be rewritten as:

$$\Delta \bar{V}_t(q) = \bar{V}(t) - (\bar{V}(l) + \bar{V}(r)) \quad (8)$$

Regression tree is formed by splitting each node until either of the following conditions is met for a node:

The greatest variance reduction of the best question falls below a pre-set threshold α :

$$\max_{q \in Q} \Delta \overline{V}_t(q) < \alpha \quad (9)$$

The number of instances falling in the leaf node t is below a threshold β .

When a node cannot be split further, it is declared a terminal node. The tree building algorithm stops when all nodes are terminal.

Regression tree is a special case of model tree. The only difference between regression tree and model tree is that for model tree each node contains a linear regression model based on some of the attribute values instead of a constant value. Linear regression model predicts the value for the instances that reach the leaf.

In addition to regression and model trees in the process of duration modeling another algorithm based on decision trees could be used. This is the REP (Reduced Error Pruning) Trees algorithm [21] developed in order to obtain the optimal tree, which means finding a minimum tree size while achieving a minimum error. In this algorithm different sets of data are also used for forming and pruning the tree, wherein the mutual ratio of the amount of data of these two sets is one of the parameters of the algorithm.

The basic idea of using meta algorithms is to make more reliable decisions by combining the output of different models [29]. There is no generally accepted preferable way of combining multiple models, so many different variations can be applied. These algorithms often contribute to the improvement of the predictive performance over a single model taking into account the observation that different algorithms perform differently in different situations. In the case of phone duration modeling, different individual phone duration models will produce different errors and the meta learning algorithm, which combines the predictions of individual models in an appropriate way, could compensate for some of these errors. Therefore, meta learning technique will contribute to the increase of the overall phone duration prediction accuracy [29].

Stacked generalization or stacking is one of the meta learning algorithms invented by David Wolpert [29]. It presents a possible way of combining multiple models of different types. Stacking introduces the concept of a metalearner. The metalearner is a learning algorithm which tries to discover how best to combine the output of the base learner or level-0 learner.

General structure of the stacking algorithm is shown in Figure 1. As one can notice in the figure, the input to the level-1 model consists of the predictions of the level-0 models. A level-1 instance has as many attributes as there are level-0 models, and the attribute values give the predictions of the base learners on the corresponding level-0 instance. The method of cross validation is usually applied for every level-0 learner, ensuring that the level-1 learner uses a full set of training data.

Numerous machine learning methods can be applied for training the level-1 model. Because most of the work is done by the level-0 models, the level-1 learner may be a simple algorithm such as a linear regression or model tree. Different machine learning techniques which are used as a level-0 learner or level-1 learner such as linear regression, model tree, CART (Classification and Regression Trees) and REP (Reduced Error Pruning) Tree were described briefly in the previous paragraphs.

Additive regression [30] is one of the meta algorithms whose application could improve the performance of standard regression techniques. This improvement is achieved by generating predictions by summing up the contributions of individual models and trying to

form an ensemble of individual models which optimizes predictive performance according to some specified criterion. In the training phase, in each iteration, a standard regression tree is formed using the residuals of the tree from the previous iteration as the training data. In the case of duration modeling the residuals represent the prediction errors, i.e., the differences between the actual and predicted values of the phone durations. In each iteration, prediction of residuals from previous iteration is performed and thus automatically the error from the previous iteration is reduced. The user-specified parameters are the maximum number of iterations and shrinkage parameter which determines the run time. The parameter α is user-specified constant value between 0 and 1 which is multiplied by the prediction value before subtracting. This reduces the model's fit to the residuals and consequently reduces the chance of overfitting. In this way, of course, the number of iterations required for the obtaining an optimal model increases.

Figure 1. General structure of stacking algorithm.

Bagging or bootstrap aggregating algorithm [31] is also one of the meta algorithms that can be applied for modeling the phone durations. This algorithm is based on a combination of predictions that give different individual models, and the final predicted value represents the mean value of the individual predictions of each model. The general structure of the algorithm is shown in Figure 2. Total number of individual models is the parameter that user specifies in advance. Each model was developed using a different training set, which is the same size as the original data set and obtained by selecting data from the original set in a random manner. Therefore, it is possible that some of the instances is repeated several times in the new data set while others can be omitted. It can be shown theoretically that averaging over multiple models developed from independent training sets always reduces the expected value of the mean-squared error [29].

Figure 2. General structure of bagging algorithm.

4. EXPERIMENTAL RESULTS

In this chapter duration models have been developed with LinearRegression (LR), M5P (model tree), M5PR (regression tree), REPTree with and without pruning, AdditiveRegression(AR), Bagging (BAG), and Stacking (STACK) algorithms of WEKA [32]. These algorithms have been used for training the models on a large speech corpus which contains 98214 phonemes including 38543 vowels and 59671 consonants. SAMPA symbols of phonemes and the number of their occurrences in the speech database for the Serbian language are shown in Figure 3. Phone duration models have been developed for the full phoneme set of the Serbian language as well as for vowels and consonants separately. 10-fold cross-validation procedure has been used to evaluate phone duration models. The evaluation of the duration models developed is carried out using objective measures such as root-mean-squared error (RMSE), correlation coefficient (CC) and mean absolute error (MAE) between the predicted and the actual durations of phones. Prediction performance of each model is also evaluated on unseen (new) data which were not used in the training phase. In this experiment, the whole database was split into two subsets: the training set and the test set. The training set contains 80% of the database and the remaining 20% instances constitute the test set.

In Figures 4, 5 and 6 RMSE, MAE and CC of all models developed for the full phoneme set in the Serbian language are shown by histograms. One can notice that AR REPTree model has achieved the best predictive performance. REPTree algorithm as the basic algorithm in AdditiveRegression gives better results than M5PR algorithm, while it was shown that the M5PR algorithm is better as basic algorithm than REPTree in Bagging algorithm. Also, one can notice that models obtained using any of the meta algorithms have better performance than the LR model or tree-based models. One can also notice that the performances of M5PR model are slightly worse than the performance of M5P model.

Table 1. Predictive performances of duration models for the full phoneme set (two different test modes)

Duration model (test mode)	RMSE [ms]	MAE [ms]	CC
LR (cross-validation)	20.8834	15.7481	0.8203
LR (20% test set)	20.8554	15.7226	0.8224
M5P (cross-validation)	15.5579	11.4724	0.9047

Figure 4. Root-mean-squared error for different duration models.

This is a very important fact because the application of M5PR model for the prediction of phone duration reduces prediction time even though the number of terminal nodes is larger than in the case of prediction by M5P model, considering the leaves of the tree contain a

constant value which is the predicted value of a given phoneme. It can be observed that the LR model has the worst performance in terms of all three quantitative measures.

Figure 5. Mean absolute error for different duration models.

Tables II and III show the values of RMSE, MAE and CC for consonant and vowel duration models, respectively. The training set is used for developing the duration models and the evaluation of the model performances is carried out on the test set. The total number of consonants in the training and test sets is 47737 and 11934, respectively. The total number of vowels in the training and test sets is 30835 and 7708, respectively. Performances of these models are comparable with the prediction performance of models obtained for the full phoneme set. Consonant duration models have achieved RMSE from 13.8348 to 16.6662 ms, MAE from 10.1952 to 12.1044 ms and CC from 0.8276 to 0.8833. Vowel duration models have achieved RMSE from 16.1226 to 19.9038 ms, MAE from 12.2446 to 15.3706 ms and CC from 0.8412 to 0.899. Consonant duration model developed using AdditiveRegression algorithm has the best performance, but in this case better results are obtained when the M5PR algorithm is used as the basic algorithm. AR REPTree vowel duration model has the best predictive performance. Using of linear regression when developing consonant duration models as well as vowel duration models also gives the worst results.

In order to improve the model performances obtained the outliers of the speech database have been removed and a new range of phone durations was obtained. This new range of durations contains 96.27% of the data for the full phoneme set and it was obtained considering the distribution of durations and the number of instances which have extremely small or extremely large durations near the boundary values of the duration range, i.e., around 2 and 290 ms (Figure 7). Phone duration distribution after removing the outliers is shown in Figure 8. The distribution of phone durations in the speech database used approximates gamma distribution. Model performances obtained for the full phoneme set after removing the outliers are given in Table 4.

In Figures 9, 10 and 11 histogram shows quantitative measures RMSE, MAE and CC obtained for the full phoneme set after removing the outliers. Based on the results obtained it can be seen that the AR REPTree model developed for the full phoneme set has again the best predictive performance. This model outperforms the second best model by approximately 1.3% and 1% in terms of relative reduction of the root-squared error and mean-absolute error, respectively. By applying linear regression method the worst performance model is obtained.

Figure 9. Root-mean-squared error for different duration models after removing the outliers.

Figure 10. Mean absolute error for different duration models after removing the outliers.

Figure 11. Correlation coefficient for different duration models after removing the outliers.

The values of RMSE, MAE and CC obtained for consonant and vowel duration models after removing the outliers are given in Table 5 and Table 6. In Figures 12, 13, 14, 15, 16 and 17 histograms present quantitative measures of these models that were obtained by removing from the speech database consonants or vowels which are located near the boundary values of the duration range. It can be seen that the application of AR REPTree algorithm, in both cases, gives the best predictive performance model, while the use of linear regression gives the worst performance models.

Figure 14. Correlation coefficient for consonant duration models after removing the outliers.

Figure 15. Root-mean-squared error for vowel duration models after removing the outliers.

Figure 16. Mean absolute error for vowel duration models after removing the outliers.

Table 7 shows the percentage of RMSE improvement yielded by removing the outliers. Based on these results it can be observed that RMSE decrease for the full phoneme set is in the range from 5.13% to 13.44%, for consonants from 3.12% to 5.91% and for vowels from 4.21% to 14.19%. Also, it can be seen that AR REPTree duration model and AR REPTree vowel duration model have the smallest decrease of RMSE in percentages. These models also represent the best predictive performance models. M5PR consonant duration model achieves the smallest percentage of RMSE decrease after removing the outliers. On the other hand, the LR model that represents the worst performance model achieves the biggest decrease of RMSE in percentages after removing the outliers for the full phoneme set as well as for consonants and vowels.

CONCLUSION

In this chapter different phone duration models for the full phoneme set as well as vowels and consonants of the Serbian language were presented. These models were developed using various machine learning techniques such as linear regression, tree-based algorithms and meta-learning algorithms. In the duration modeling procedure a large speech corpus containing 98214 phonemes was used. Removing of outliers was carried out in order to improve model performance. The objective evaluation of the models obtained for the Serbian language was performed. The quantitative measures obtained in terms of RMSE, MAE and CC show that AR REPTree model is the best predictive performance model for the full phoneme set as well as vowels and consonants.

In the future, we intend to implement the duration models developed in the speech synthesizer for the Serbian language [25] and to perform subjective evaluation tests of our duration models in order to estimate the quality of synthesized speech on the basis of qualitative measures such as naturalness and intelligibility of speech.

ABSTRACT

Purpose: Inferential comprehension is an important aspect of language development in the early years and is strongly associated with future academic success. Yet, this language ability has not been extensively documented in young children with SLI. Information in that regard would be helpful in guiding assessment and intervention in speech-language pathology. This study aims to collect data on inferential abilities of 5-year-old children with SLI.

Methods: Sixty-four children, distributed in three groups, participated in the study: 16 children with SLI were compared to 26 age-matched and 22 language-matched typically developing children. Inferential abilities were examined with pre-determined questions inserted into a dialogic reading task. The performance of the three groups of children was compared according to the inference types and the quality of responses provided.

Results: Children with SLI obtained similar results to the younger language-matched group and weaker results than the age-matched group. Significant differences among the three groups were observed for both inference types and quality of responses.

Conclusions: This study provides new information about the inferential abilities of children with SLI and typically developing children aged 4 to 5 in the context of dialogic

reading. The results offer some foundation for planning assessment and intervention in the area of inferential comprehension with young children.

Keywords: language comprehension, inferences, preschool children, specific language impairment

INTRODUCTION

Children with specific language impairment (SLI) “have a significant and longstanding deficit in spoken language ability that adversely affects their social and academic well-being” (Leonard, 2014). An important academic challenge for these children is learning to read including the various elements leading to and involved in reading comprehension (Catts, 2009; Gough & Tunmer, 1986; Nation & Norbury, 2005). In this chapter, we focus on a well-known precursor of reading comprehension, i.e., oral comprehension abilities (Cain & Oakhill, 2007). More specifically, this chapter examines inferential comprehension in young children with SLI.

Inferential comprehension is the ability to “read between the lines”, a process that integrates linguistic knowledge (words and grammatical rules) with the social and contextual knowledge of the person who interprets a message (Letts & Leinonen, 2001; Paul, 2000). Thus, inferential comprehension comes into play when one has to interpret information that is not explicitly presented (Adams, Clarke, & Haynes, 2009; Bishop, 1997; Botting & Adams, 2005; van Kleeck, 2008). Another characteristic of inferential abilities is that they tap into skills, such as working memory or executive functions (Adams et al., 2009; Norbury & Bishop, 2002), facilitating the link between language skills and world knowledge to understand the expectations, motivations and intentions of the speaker (Makdissi & Boisclair, 2006; Paul, 2000).

One of the challenges of studying inferential comprehension in young children is measuring it in a valid and reliable fashion. To that end, dialogic reading is the preferred methodology (Filiatrault-Veilleux, Bouchard, Trudeau, & Desmarais, accepted) because, when an adult shares a book with a child by telling the story and asking questions, it encourages the child’s participation and interest and stimulates comprehension of the story (Ford & Milosky, 2008; Makdissi & Boisclair, 2006; van Kleeck, Vander Woude, & Hammett, 2006; Wenner, 2004; Whitehurst & Lonigan, 1998). In this type of activity, the child’s inferential abilities support the construction of a coherent mental representation of the story based on the information provided and on links to the child’s world knowledge (Ford & Milosky, 2003; Joffe, Cain, & Maric, 2007). Furthermore, dialogic reading has been shown effective in promoting the development of inferential comprehension (van Kleeck et al., 2006) as well as contributing to language development as a whole (Price, van Kleeck, & Huberty, 2009). It allows young children to engage in the process of reading and to be active in the construction of the meaning of the story (Makdissi & Boisclair, 2006; van den Broek, Tzeng, Riden, Trabasso, & Basche, 2001). Consequently, dialogic reading is a facilitator of language development. It is therefore a concern that children with SLI are less exposed to language in the inferential context of dialogic reading than typically developing children (van Kleeck et al., 2006). Indeed, observations of dialogic reading show that parents of children with SLI do not optimally adjust their language to the level of language of their child (van

Kleeck, 2008). This is an observation that encourages the pursuit of investigating inferential comprehension in young children with SLI.

To read between the lines and understand a story, various types of inferences can occur. In this study, we focus on two categories of inferences (Table 1). The first category, called “causal inferences”, is considered obligatory and contributes to the comprehension of the causal structure of the story, i.e., the story grammar elements comprised of the setting, the initiating event, the problem, the goal, the internal response of the character, the attempts at solving the problem and the final solution (Mandler & Johnson, 1977; Stein & Glenn, 1979). This category of inference is hierarchically related to elements of story grammar (Kendeou, Bohn-Gettler, White, & van den Broek, 2008; Makdissi & Boisclair, 2006; van Kleeck, 2008). Inference types of this category can target the internal response or emotion of the character, the initial event, the problem, the attempts to solve the problem, the predictions of the next logical step of a sequence of events and the solution. The second category of inferences is not critical to story comprehension but contributes to enrich the representation of the story via connections made with knowledge of the world (Bowyer-Crane & Snowling, 2005). This category of inference is called “informational inference” or “inferences based on world knowledge” (Cain & Oakhill, 1999; van Kleeck, 2008). This second category allows children to make the connections between their own world knowledge and explicit information contained in a message. For example, informational inferences can target the setting of the story or the definition of new words. Both categories of inference (causal and informational inferences) play an important role in the construction of the mental representation of the story. In fact, the ability to make inferences is crucial in understanding a story. It develops prior to school entry and serves as an important foundation of reading comprehension in subsequent years (Filiatrault-Veilleux et al., accepted).

In children with SLI, early research about inferential comprehension studied school aged participants once they were already experiencing reading comprehension difficulties. The results showed that, when compared with typically developing (TD) peers, children with SLI have difficulty making inferences (Adams et al., 2009; Bishop, 1997; Botting & Adams, 2005; Bowyer-Crane & Snowling, 2005; Dodwell & Bavin, 2008; Ryder, Leinonen, & Schulz, 2008). For example, the results of children with SLI aged 6 to 11 years old are on par with those of younger TD children in tasks involving inferential language abilities (Adams et al., 2009; Bishop, 1997; Botting & Adams, 2005). According to Norbury and Bishop (2002), children with language problems rely on some inferential abilities, but they have difficulty making inferences that require linking the context and world knowledge. As inferential comprehension is a critical ability for subsequent development of reading comprehension (Bishop & Adams, 1990; Catts, 2009; Lynch & van den Broek, 2007; Serpell, Baker, & Sonnenschein, 2005), the presence of difficulties in understanding inferences is a risk factor for these children. Some authors suggest that for young children with SLI, these difficulties may be due to limits in accessing world knowledge or difficulties in comprehension of grammar rules that affect the processing/understanding of sentences (Adams et al., 2009; Bishop, 1997). According to Bowyer-Crane & Snowling (2005), this challenge could be greater for certain types of inferences that involve an interpretation based on world knowledge. Children’s performance could also be explained by a difficulty inhibiting information not relevant to meaning, a difficulty in constructing complete mental representations (Bishop, 1997; Ford & Milosky, 2008) or an inability to select relevant information to make an inference (Cain, Oakhill, Barnes, & Bryant, 2001).

Some studies also investigated inferential comprehension in younger children with SLI. In recent years, Ford and Milosky (2003, 2008) as well as Spackman, Fujiki and Brinton (2006) compared language impairment children to TD children on the ability to infer the internal response of characters. These studies concluded that, even in 4 to 6 year olds, and thus prior to school entry, children with language impairment have difficulty inferring the emotional response of the character in a story. It is also interesting to note that intervention targeting the comprehension of inferences has some positive effects. For instance, a study by van Kleeck and al. (2006) looked at the effect of book-sharing intervention on both literal and inferential comprehension of preschoolers aged 3 to 5. These children, with identified language impairments and low socioeconomic backgrounds, made gains in language comprehension abilities following the intervention. Another study, carried out with young francophone children with SLI, also showed an improvement of inferential comprehension following intervention (Desmarais, Nadeau, Trudeau, Filiatrault-Veilleux, & Maxes-Fournier, 2013). Taken together, the results of these studies suggest that inferential comprehension in SLI children aged 4 to 6 is an ability that warrants further investigation and that it is important to consider inferential comprehension when planning intervention with these children.

The studies published to date provide information about some of the difficulties in inferential comprehension experienced by young children with SLI. However, more investigations are necessary to better understand this phenomenon and to provide more solid foundation for planning assessment and intervention for these children. Namely, knowing how young children with SLI perform on different types of inferences, e.g., on causal versus informational inferences, would offer a better picture of their comprehension abilities. In addition, very few studies to date have examined the types of responses provided by children with SLI during an inferential task (Adams et al., 2009; Barnes, Dennis, & Haefele-Kalvaitis, 1996; Gnepp & Gould, 1985; Spackman et al., 2006). Yet, this data could be extremely relevant in the clinic enabling speech language pathologists in every day practice to follow the progression of children with SLI and allowing for better documentation of children's performance.

Table 1. Classification of inference in the context of a narrative

Category	Inference Type	Examples of questions that lead to the inference
Inference hierarchically Related to elements of story grammar - Causal inferences	Trigger	What is the protagonist's problem?
	Internal response	How does the protagonist feel?
	Goal	What does the protagonist want? What is he looking for?
	Problem-solving attempts	What could the protagonist do?
	Prediction	What will happen? Why?
	Consequences/solution	Was the protagonist's goal achieved?
Inference Based on World Knowledge – Informational inferences	Setting (character/place/time)	Who is in the story? Where is this happening? When (day/year/season...) is this story taking place?
	Definition/word meaning	What do you think this word means?

Bowyer-Crane & Snowling; 2005; Makdissi & Boisclair, 2006; van Kleeck, 2008.

This study therefore aims to further the understanding of inferential comprehension in 5-year-old children with SLI in the context of dialogic reading. To do so, we compare children with SLI to age-matched (5 years-old) and language-matched (4 years-old) TD children on a task of inferential comprehension and pursue three objectives. The first objective is to compare the global performance of SLI to both groups of TD children on an inferential comprehension task. The second objective is to verify whether there are differences between children with SLI and TD children on the results obtained when making causal inference and informational inference (based on world knowledge). The third objective is to compare the quality of responses of children with SLI to TD children.

METHOD

Participants

This study, approved by the Research Ethics Committee of the Institut de réadaptation en déficience physique de Québec (IRDPQ), uses a controlled comparison intergroup design (Myers & Well, 2003). Sixty-four children in the Quebec City area of Canada were recruited for the study. Three groups were formed. The experimental group was comprised of 16 children with SLI (mean age: 5;3). The diagnosis of SLI was based on the definition used in the province of Quebec, i.e., severe language impairment characterized by deficits in at least two language components in the absence of an intellectual or sensory impairment. These children had thus met the criteria that determine eligibility for services to children with SLI at the IRDPQ and were currently receiving therapy from that institution. Two comparison groups of typically developing children were also included in the study, i.e., 26 age-matched (mean age: 5;0) and 22 language-matched (mean age: 4;0). The score on the Échelle de Vocabulaire Imagé Peabody (ÉVIP), the French Canadian version of the Peabody Picture Vocabulary Test - PPVT (Dunn, Thériault-Whalen, & Dunn, 1993) was used to form the language-matched group. The ÉVIP is shown to have good reliability ($r = 0.91$ to 0.94). Information about the three groups of children is provided in Table 2. The SLI group was recruited in collaboration with the IRDPQ. Children in the two comparison groups were recruited from previous research projects, through the collaboration of daycare centers and via advertisements on a university e-mail list. A parent checklist confirmed that these children did not present with language or other developmental difficulties.

MATERIAL

The experimental dialogic reading task measuring inferential language abilities was developed using the criteria described by van Kleeck and al. (2006). A book entitled *Pig gets lost* (Amery & Cartwright, 2001) was selected for the task because of its length, the quality of its illustrations, and the amount of predictions children could make throughout the story. Twenty questions were asked orally to the child while reading the story. Ten addressed literal content and ten measured inferential comprehension. Literal questions were included to preserve the naturalness of the activity and to ensure the child some success. All the questions

were integrated into the book to ensure that participants were assessed in both a standardized and a natural manner. Only the data obtained on inferential questions is reported in this study. The inferential questions in the story targeted two different categories of inferences, as defined before, based on the categorization proposed by van Kleeck (2008) and Bowyer-Crane and Snowling (2005) (Table 1). Five questions targeted causal inferences related to story structure. An example of an internal response question in our task was: "How do you think Ms. Dupre feels after finding *her piggy*?" It is appropriate to infer that Ms. Dupre is happy, since she found the lost pig. Five questions targeted informational inferences based on world knowledge. For example, the interpretation of "Why do pigs live in a pen?" was based on world knowledge and required that the child know that a pen is used to protect animals or prevent them from escaping. Each of the ten questions is scored on a scale of 0 to 3 according to the quality of response provided by the child. The total score obtained is out of 30. The rating system used for this instrument was developed based on the four-level system used in the Preschool Language Assessment Instrument - Second Edition [PLAI-2] (Blank, Rose, & Berlin, 2003) and is extensively described in a previous publication (Desmarais et al., 2013). Children's responses were coded as "expected - 3 points", "acceptable - 2 points", "ambiguous - 1 point" or "inadequate - 0 point". The codes and their descriptions are presented in Table 3 (see Appendix A for examples of responses obtained by participants).

Table 2. Characteristics of participants

Participants	SLI (<i>N</i> = 16)	Age-matched (<i>N</i> = 26)	Language-matched (<i>N</i> = 22)
Gender	8 girls 8 boys	14 girls 12 boys	9 girls 13 boys
Mean age ^a (SD ^b)	5.3 (0.4)	5.0 (0.2)	4.0 (0.1)
EVIP (SD ^c)	4.9 (1.4)	6.7 (1.3)	4.6 (1.5)

^a Mean age is presented as follows: year, month.

^b Standard deviation of mean age.

^c Standard deviation of mean age at EVIP.

Table 3. Definitions and score given for each type of response

Response Type	Definition	Score
Expected	The answer given by the child is entirely targeted by the question.	3
Acceptable	The answer given by the child makes sense, but does not match the target response of the question: it is imprecise, not directed toward the focal point of the question, or includes irrelevant information.	2
Ambiguous	The answer given by the child contains relevant information, but is too vague, too specific or is not directly related to what is expected.	1
Inadequate	The child does not answer the question or gives an answer that is not related to the question.	0

The participants' first responses were coded and no feedback was given to the child. However, in some instances when the information was necessary to understand the story, some cues were provided so that the child could complete the task. To limit the impact of expressive difficulties for the children with SLI, the classification of the answers did not take into account the formal aspects of the responses (i.e., phonological processes, syntax or length of sentences). To ensure reliability of the coding system, a blind inter-rater analysis was performed on 15% of the total data ($n = 11$). Correlation of the two judges' ratings was high ($r = 0.951$, $p < 0.001$), suggesting adequate inter-rater reliability.

PROCEDURE

The data used in this study are part of a broader research project designed to assess language comprehension of 5-year-old with SLI and compare it with typically developing children. To collect the data, a 90 minute session was scheduled and conducted by research assistants in the *Centre interdisciplinaire de recherche en réadaptation et intégration sociale (CIRRIS)* of IRDPQ. Research assistants were trained in the administration of the materials and procedures. The interview was filmed to facilitate the transcription and the analysis of the children's responses as well as the inter-rater reliability. This study reports on the results of the experimental task designed to measure inferential language abilities of the participants.

DATA ANALYSIS

An analysis of variance (ANOVA) was conducted to compare the mean scores obtained by the three groups in order to compare (1) total score of inferential abilities, (2) types of inferences and (3) the quality of responses to inferential questions. Based on the significant differences that emerged, post hoc analysis using a Tukey test were performed. An alpha level of 0.05 was used to determine significance of the differences observed.

RESULTS

The scores obtained by the three groups of children in the inferential comprehension task are reported in Table 4. A scatter plot presenting the performance of participants and the means obtained by each group is shown in Figure 1. For the first objective, the mean total score on the task was compared across groups. A significant difference between groups was demonstrated for inferential comprehension scores ($F(2, 61) = 3.392$, $p = 0.040$). Post hoc analysis using the Tukey test showed that the performance of children with SLI was significantly lower than age-matched children (Tukey's honestly significant difference (HSD) 4.46, $p = 0.05$). However, no significant differences were observed between the performance of children with SLI and language-matched children (Tukey's HSD = 1.02, $p = 0.861$). Finally, no significant differences were observed between the language-matched and age-matched children for inferential comprehension scores (Tukey's HSD = 3.44, $p = 0.123$).

To address the second objective, we compared the groups' scores on the two categories of inferences, i.e., causal and informational inferences. These results are also reported in Table 4 and illustrated in Figure 1. A significant difference between groups was observed only for informational inference category (Informational: $F(2, 61) = 4.544$, $p = 0.014$, Causal: $F(2, 61) = 1.265$, $p = 0.289$). Post hoc analysis using the Tukey test showed that the children with SLI and language-matched children scored significantly lower than age-matched children for this category of inference (SLI: Tukey's HSD = 2.70, $p = 0.026$ and Language-matched: Tukey's HSD = 2.21, $p = 0.05$).

Table 4. Means and standard deviations obtained by each group on the two categories of inferences

	SLI (S) (<i>N</i> = 16)	Age-matched (A) (<i>N</i> = 26)	Language- matched (L) (<i>N</i> = 22)	<i>p</i> value
Inferential comprehension				
Raw score / 30 (SD)	14.34 (5.54)	18.80 (6.89)	15.36 (4.93)	S*< A = L
% score (SD)	46.92 (18.53)	62.66 (22.98)	51.28 (16.29)	
Informational inferences				
Raw score / 15 (SD)	4.88 (2.53)	7.58 (3.76)	5.36 (2.85)	S*= L* < A
% score (SD)	32.50 (16.84)	50.51 (25.10)	39.05 (18.93)	
Causal inferences				
Raw score / 15 (SD)	9.47 (3.61)	11.22 (3.74)	10.00 (3.75)	S = A = L
% score (SD)	63.13 (24.08)	74.82 (24.93)	66.67 (25.02)	

* $p \leq 0.05$; ** $p \leq 0.01$.

=: no statistical difference between groups < or >: statistical difference between groups.

Table 5. Mean number of responses in each category of inferential questions for the three groups of children, variances and standard deviations

Response Types	SLI (S) (<i>N</i> = 16)	Age-matched (A) (<i>N</i> = 26)	Language- matched (L) (<i>N</i> = 22)	<i>p</i> value
Expected	3.38 (1.58)	5.00 (2.33)	3.77 (1.34)	S* < A = L
Acceptable	1.31 (1.01)	1.11 (0.95)	0.86 (0.83)	S = A = L
Ambiguous	1.50 (0.82)	1.04 (1.00)	1.82 (0.91)	L* > A = S
Inadequate	3.75 (2.24)	2.62 (2.56)	3.31 (1.96)	S = A = L

* $p \leq 0.05$; ** $p \leq 0.01$.

=: no statistical difference between groups < or >: statistical difference between groups.

*Group significantly lower.

Figure 1. Scatter plot presenting participants' scores and the means obtained by each group.

*Group significantly lower + Group significantly higher.

Figure 2. Mean number of responses for each category of inferential questions for the three groups of children.

For objective 3, to analyze the quality of responses provided by the participants, a score representing each category's number of responses (expected, acceptable, ambiguous and inadequate) was calculated. It should be noted that this analysis of the quality of the children's responses relies on the same data as the analysis for objective 1. Mean score for each category was calculated independently for the three groups of children. The mean number of responses obtained by category are reported in Table 6 and Figure 2 shows a scatter plot of the performance of the participants. The ANOVA revealed a significant difference between groups for the "expected" responses ($F(2, 61) = 4.539, p = 0.015$) and for the "ambiguous" responses ($F(2, 61) = 4.306, p = 0.018$). Post hoc analysis using the Tukey test showed that the children with SLI gave significantly less "expected" responses than the age-matched group (Tukey's HSD = 1.63, $p = 0.021$). However, no difference was found between groups for the "acceptable" responses ($F(2, 61) = 1.116, p = 0.334$) and the "inadequate" responses ($F(2, 61) = 1.316, p = 0.276$). Finally, with regards to "ambiguous" responses, language-matched children provided significantly more "ambiguous" responses than age-matched children (Tukey's HSD = 0.78, $p = 0.014$).

DISCUSSION

The aim of this study was to compare the performance of 5-year-old children with SLI to age-matched and language-matched children in a dialogic reading task measuring inferential language abilities. Our results underscore some differences between the groups with regards to the category of inferences that are mastered by TD children and those mastered by children with SLI. They also inform us about the quality of responses provided by young children in an inferential comprehension task. With regards to inferential ability, a striking observation is that the 5 year old children with SLI had significantly more difficulty making inferences than TD peers of the same age. Our results are consistent with previous research based on school-age children with SLI (Adams et al., 2009; Bishop, 1997; Botting & Adams, 2005; Bowyer-Crane & Snowling, 2005; Dodwell & Bavin, 2008; Ryder et al., 2008). In addition, the results show that children with SLI, as young as 5 years old, prior to school entry, present with difficulties in inferential comprehension. In addition, as predicted by Adams and al. (2009), Bishop (1997) and Botting and Adams (2005), our data reveal that the inferential abilities of the children with SLI are comparable to those of the younger TD children. These results add to accumulating evidence that the performance of children with SLI is quite different from that of TD children. As previously mentioned, TD children as young as 4 years old exhibit good inferential abilities in dialogic reading tasks. According to studies on the development of the inferential ability during the early childhood period (Adams et al., 2009; Blanc, 2010; Ford & Milosky, 2008; Gnepp & Gould, 1985; Makdissi & Boisclair, 2006; Wenner, 2004), the ability to make inferences emerges around the age of 3 or 4, is further refined between the ages of 4 and 6 and continues to improve with maturation. Thus, it is clear that the ability to make inferences is emerging during the preschool period (Kendeou et al., 2008; van Kleeck et al., 2006) and that supporting the development of this ability at that age is reasonable.

Our study included an in depth examination of causal inferences. For this category of inference, the three groups of children investigated in this study performed well. This

confirms, as suggested in previous works (Deconti & Dickerson, 1994; Ford & Milosky, 2008; Makdissi & Boisclair, 2006; Wenner, 2004), that preschool children, as young as 4, are clearly able to make this category of inference. This could be explained by the fact that causal inferences related to story structure are likely often used by parents and educators while reading a story. It has been suggested that caregivers spontaneously establish a conversation with children around the problem that characters face in a story whereas they do not often discuss word definitions, an informational inference based on world knowledge (van Kleeck, 2008). Finally, the presence of a visual support during the task could have facilitated children's ability to answer causal inference questions related to story structure. For example, when answering a question such as the emotion experienced by a character, children can rely on the facial expression of the character to make an inference.

Turning to informational inferences based on world knowledge, our results show that the children with SLI and the younger TD group had more difficulty understanding world knowledge inferences. This finding is consistent with what Bowyer-Crane and Snowling (2005) obtained with school-age children. This type of inference requires interpreting a message using acquired world knowledge. Indeed, as Bowyer-Crane and Snowling (2005) and Cain and Oakhill (1999) note, children with poorer comprehension have more difficulty accessing their world knowledge when they perform a task. It has been suggested that problems of access to world knowledge could actually impede the construction of a coherent mental representation of a story and hinder the comprehension of inferences (Adams et al., 2009; Bishop, 1997). Moreover, some authors have investigated the general knowledge deficits as a source of inference-making difficulties (Barnes et al., 1996). This being said, when world knowledge is controlled, children with poor comprehension abilities present more difficulties in making inferences (Cain et al., 2001; Cain & Oakhill, 2007). It appears that it is not the lack of knowledge but the ability to retrieve knowledge and information that presents a challenge for these children.

Furthermore, we explored this subject further by going beyond the children's scores on the task in order to shed light on the quality of their responses to inferential questions. To address the third objective, we found that children with SLI gave significantly less expected responses than the children in the two TD groups. Again, these results suggest that understanding inferential questions is more difficult for these children which results in a fewer number of target responses. However, as it is impossible to completely isolate receptive and expressive difficulties in this task, it is likely that expressive limitations could have influenced the children's ability to produce complete and accurate answers. Another interesting finding is that the younger TD group provided more "ambiguous" responses than the two other groups. The responses of the younger children differ from those of the other two groups in that they are less complete and not always directly related to the expected response. In general, the TD 4-year-olds in this study attempted to answer and elaborate, even if their responses were not related to what was expected. This strategy differed from that of children with SLI children who tended not to answer. It is possible that children with SLI would rather not talk if they are unsure about their answer. This could be explained by the observation that children with SLI are aware of their language difficulties, an awareness that is linked to a reduction in verbal production (Jerome, Fujiki, Brinton, & James, 2002; Lindsay & Dockrell, 2000).

Some strengths and limitations of the current study must be underscored. As previously mentioned, little research has examined inferential abilities of preschool children with SLI.

One of the strengths of the present study is that it extends knowledge about inferential comprehension in SLI. Our results point to some areas of relative difficulty for children with SLI including making inferences based on world knowledge and providing answers that are close to the target response. These new data, collected on an aspect of language that has not been extensively studied in young children with SLI, provide information that can later be integrated in the assessment and intervention of these children. We acknowledge some limitations of the current study. First, the execution of this experimental task was conducted at the end of a testing session. Therefore, it is possible that fatigue influenced the behaviour and performance of some children (attentional capacity, reduced collaboration, loss of interest, etc.). In future research, it would be better to administer the task earlier during the assessment in order to avoid this possible effect. Second, as mentioned earlier, separate expressive and receptive abilities in children during a highly ecological task is a challenge. Thus, it is likely that the difficulties with expressive language in children with SLI might have an impact on the measure of the inferential abilities.

CONCLUSION

This study contributes to a better description of inferential language abilities in young children with SLI. The results are helpful in refining the expectations of researchers and clinicians regarding the performance of young children with SLI on inferential comprehension tasks. The study also offers some elements of foundation for planning better intervention for these children, especially with regards to documenting the quality of responses provided by children when answering questions relating to inferential comprehension. Finally, this study highlights the value of dialogic reading as a highly natural and familiar task that can also be carried out in a standardized manner.

ACKNOWLEDGMENTS

This research was supported by a grant from the *Fonds québécois de recherche sur la société et la culture* (2008-2011) to Chantal Desmarais. We are grateful to the research assistants involved in data collection and data analysis and to M. Jean Leblond for consultation on the statistical analyses performed. We would also like to extend our thanks to the children and families who participated in the study.

APPENDIX A

Sample of responses obtained to the world knowledge inference question “Why do pigs live in a pen?”.

Types of responses	Examples
Expected	"To prevent them from escaping." / "So they do not get lost."
Acceptable	"So they can eat." / "So it does not dirty the house."
Ambiguous	"Because it's a farm." / "Because they love the mud."
Inadequate	"I do not know." / "Because."

Chapter 8

VIRTUAL AVATAR SIGNING IN REAL TIME AS CLASSROOM SUPPORT FOR DEAF STUDENTS

Institute of Robotics (IRTIC), University of Valencia, Valencia, Spain

ABSTRACT

This chapter describes a speech and text translator from Spanish into Spanish Sign Language, trying to solve some of the problems that deaf people find when they try to access and attend to specific training courses. The application uses the voice as input for translation, but it also translates text from PowerPoint slides used by the teacher to explain the lesson concepts. In addition to the translator system, a virtual avatar has been created and integrated in the final application to visually represent the signs translation. A set of real-time avatar animations representing the signs are used, with individual words and common used phrases in the training environment. The process to create, adapt and reproduce the movements and mix them in real time is described. The tool is based on a client/server architecture where teacher and deaf students have their own application to help both in teaching and learning during a class session, also facilitating the communication between them using a chat. The system can be used in courses where deaf and hearing people are sharing the same material and classroom, so deaf people can attend and follow the class without problems, improving the integration of this group of people to specific academic areas. The tool has been tested to obtain direct information with a group of deaf people from the Deaf Association of Seville.

Keywords: Virtual Sign Animation, Speech to Gesture Translation, Virtual Characters, Avatar Animation

INTRODUCTION

The constant evolution of computers and portable devices make it possible to develop applications to help impaired people in some aspects of their life. This is the case of deaf people. In the field of computer graphics, some efforts have been made to develop systems that help hearing impaired people in their communication difficulties.

The tools that have been developed help deaf people to communicate with ordinary people through the computer. Some of them are intended to develop gesture to speech systems to translate a sign language to a spoken language, while others go in the opposite direction, translate text or speech to a sign language by means of virtual avatar animations representing the signs.

These systems have two main problems to solve: (1) to translate a speech or written text from a language to a sign language; (2) to create movements for the virtual avatars that can be, at least, understandable by deaf people (Kipp, 2011), and, even better, with a certain level of fluency. These problems are addressed in the present research.

An additional problem is the existence of many different sign language standards, as there is no standard not even in any given country, so the efforts made on a system to translate from one specific language are not always suitable for other languages.

In this chapter a speech and text translator from Spanish into Spanish Sign Language, *Lenguaje de Signos Español* (LSE) is addressed. Moreover, the process of creating a virtual avatar signing in real-time is described. The result of the research is applied to solve some of the problems that deaf people find when they try to access and attend specific training courses, sharing the class with hearing people.

Thus, when a company offers different training courses (for example, for unemployed people) and they have to adjust the cost of each course, it is difficult for deaf people to enroll in these courses because of the costs associated to hiring a translator. This can be harder if there are several hearing people and a small group of deaf people interested in the course. If a special sign language application for deaf students is offered, where they can follow the lessons in sign language sharing the class with other people, this can become a good starting point to improve their integration. If this application also tries to help in the communication between deaf person and teacher, increases the opportunities offered by the tool.

This is the main objective of the present research. An automatic system for translating Spanish to LSE has been developed which supports the simultaneous translation of voice and PowerPoint presentations to LSE. There is also an avatar signing in real time (RT), and a special chat between deaf students and his/her teacher who can or not have knowledge of LSE.

In a literature review, which will be detailed in the next section, authors have not found applications with the same purpose using virtual avatars signing in real time.

The chapter is organised as follows: Section 2 shows a review of the literature. Section 3 presents the system architecture. Section 4 and 5 describe the different modules and the interface in detail. Section 6 explains the main problems and our solutions. Sections 7 and 8 show the evaluation results, the main conclusions and future work.

RELATED WORK

After a revision of the current literature, we have classified the different efforts made to keep communication between deaf people and hearing people. Some researchers have focused their work on gesture recognition, trying to automatically recognize a sign from a specific sign language. Liang (Liang, 1998) developed a Taiwanese Sign Language interpreter. This system uses a DataGlove for capturing gestures, and solves the problem of end point detection in a stream of gesture. Using hidden Markov models, the system recognizes in real time an average rate of 80% out of 250 words in their lexicon. Much in the same way, other authors have developed systems for sign language gesture recognition of other languages, using different approaches. For instance, the method developed by Sagawa (Sagawa 1998, Sagawa 2000) to automatically interpret Japanese Sign Language where a sign gesture is recognized using segmentation of words, or an American Sign Language recognizer system using video to track the user's hands (Staner, 1966). Other researchers have focused their work on developing systems that automatically translate into a sign language (Maasaki, 1996), most of which use virtual avatars to represent a speech or a written text in a sign language.

One of the main projects in this research line is VISICAST (Bangham, 2000), which translates English text into British Sign Language. The main effort of this project has been to process natural language by means of a parser that identifies functional words and resolves ambiguities by using an SGML notation (Elliot, 2000; Safar, 2001). Once a text is translated, signs are displayed using computer animation of a Virtual Avatar in two steps. First, by means of a high fidelity motion capture system a human signer is recorded. Second, a post-processing tool is used, which decomposes the captured sequence into individual signs. This system can be applied to subtitle television programs or create web pages (Verlinden, 2001).

Other projects of the same research group use virtual signing technology. In eSign, avatars are used to create signed versions of websites (Verlinden, 2005), and in the SignTel avatars are added to a computer based assessment test that can sign questions for deaf candidates. In eSign project (Zwitterslood, 2004), instead of using motion capture to generate the avatar animation, a temporal succession of images is used, each of which represents a static posture of the avatar. The signs are described through a notation for Language Signs (HamNoSys), which define aspects of hand position, speed and gesture amplitude.

Research with Japanese Sign Language (JSL) has been also made, such as Kuroda (Kuroda, 1998) who developed a telecommunication system for sign language by utilizing virtual reality (VR) technology, which enables natural sign conversation on an analogue telephone line.

Kato (Kato, 2011) uses a Japanese for a JSL dictionary with 4,900 JSL entries that have an example-based system to translate text. After that, the system automatically generates transitional movements between words and renders animations. This project is intended to offer TV services for deaf people, especially in case of a disaster, when a human sign language interpreter is not available. In this research a number of deaf people have been asked to watch the animations pointing out its lack of fluency as sign language (Akihabara, 2012).

Regarding Spanish Sign Language, San-Segundo (San-Segundo, 2012) describes a system to help deaf people when renewing their Driver's License. Such system combines three approaches for the language translator: an example-based strategy, a rule-based

translation method and a statistical translator that uses VGuido virtual animations. Thus, to create a sign animation, an XML application which supports the definition of sign sequences is used, which mixes static gestures with movement directions. After that, a movement generation process computes the avatar's movements from the scripted instructions.

After the literature revision, it seems that researchers have not found applications for the same purpose that use virtual avatars signing in real time.

SYSTEM ARCHITECTURE

As we mentioned above, this application tries to improve and facilitate the communication between a deaf student and a teacher in an academic area, not only providing a translation of voice and PowerPoint presentations in LSE, but also offering a special chat where they can communicate in both directions in an understandable way. This will improve the deaf people's access to specific training courses. For this reason, the architecture implemented is based on a client-server structure, with the main application in the teacher side and the client application in the student side (Figure 1).

The main application (teacher side) is a system based on a hierarchical architecture, where each module is responsible for a specific part in the translation, communication and visualization process.

Figure 1. Client/Server architecture.

In the student side (client), the application centres its functionality on the communication process, including the translation shown to the student both in text and LSE format through a signing avatar, and the chat for communication purposes. The main module of each application is shown in the following diagram (Figure 2).

Figure 2. Modules included in each application.

Focusing our attention in the teacher application (because the modules used in the student side are similar to those used in the teacher side), the architecture is divided in five different modules (Figure 2):

- *Speech to text module*: connected to the voice input, receives the voice and extracts the words, producing a collection of words separated in sentences.
- *PPT to text module*: receives a collection of slides from a PowerPoint presentation, producing a collection of sentences associated with each slide and a collection of words in each sentence.
- *Spanish text to sign language translator*: this is the most important module. It receives a sentence from the previous modules and using a “rule-based method” and an “analogy method”, produces a translated sentence to the LSE.
- *Avatar System module*: controls and animates the avatar using a database of movements (vocabulary). From the LSE sentence generates the correct animation movement and shows it to the user in real time.
- *Communication module*: receives all the information to be communicated to the other applications and sends the correct messages using sockets. This module is also used by applications for control and synchronization purposes.

In the following section each module is described.

SYSTEM COMPONENTS AND FUNCTIONALITY

From the global architecture, introduced in the previous section, five main modules are described in the following subsections (Figure 2).

Speech to Text Module

The Speech to text module is the responsible for collecting the audio (voice input) from the microphone connected to the computer, analyse the information and transform it into the corresponding text. Contains two main elements, a Speech recognizer to analyse the voice input and a Message system to manipulate the text data.

The Speech recognizer is responsible for generating a collection of words or sentences from a voice input that serve as input to the following modules. This module uses Microsoft Speech SDK 5.1, included in every Windows 7 installation by default. This software has the advantage that it does not need to be installed and configured by users and, it can be also easily trained, being able to learn and improve the recognition patterns as the software is being used. Before selecting this option, we have analysed different possibilities of current recognizer systems, and we have selected this option because of its easy installation, simplicity of usage, the API to communicate with our application and the training possibilities for improving the recognition. The only limitation associated with this software is that it only can be used under computers with Microsoft Windows Operating System.

Associated with the usage of this recognizer software in our application, the main problem found in the recognition process is how to detect when a sentence starts and finishes. The recognizer can provide all the words it collects from the microphone, but it is important to have the complete sentence so as to determine the best method to be applied for translation. In Section 6 we analyse the problem and explain the solution.

The Message system is responsible for showing the sentences involved in the translation process in the interface. In the application a “debug mode” is included so that it is possible to control the results of the different steps of the translator. This is useful because users can detect if there has been any mistake or problem in the recognition step or later, stay informed about all the intermediate steps of the translation process and act accordingly to solve any problem.

PPT to Text Module

A PowerPoint presentation (PPT) is a very important complementary piece of information for the speech in class. In our case it can help and solve the possible mistakes that the recognizer can make when recognizing oral explanations. Some deaf people cannot read and, therefore, it is necessary to provide a translation of the PPT that gives deaf students all the information taught in class. For that reason, a PPT translator to sign language is included in the system.

The PPT to text module reads the PPT opened by the teacher for one specific session; then, a collection of sentences in each slide is extracted and analysed for obtaining the

collection of words contained in each sentence. The translation module (Section 4.3) applies different rules and obtain one or more possible translations for that sentence, selecting one as a default (depending on a measure of the probability of success).

We include in our application a Slide Editor with a wizard so as to facilitate the revision and correction of the PPT conversion into LSE (Figure 3), where it is possible to see the different possible translations offered by the system.

The teacher can review the translation associated with each slide and can change between the offered options or specify (write) a better new one. This can be made by the same teacher or with help of a person that has LSE knowledge.

Also, by using this wizard it is possible to determine which words need to be spelled in each sentence and how they will be spelled in the translation. The revision changes can be saved to be later used for the PPT translation in the application, allowing the teacher to previously prepare the classes and review all the material out of the class session.

Figure 3. Slide Editor wizard interface.

Because using all the class material (PPT, LSE translation application, etc.) can be complicated for the teacher during the session, a remote control is also provided, which is helpful not only to manage the application, but also the global PowerPoint presentation shown to all students on the main screen. With this, the teacher can change in the program between slides, phrases in the slide and between PPT and speech as a resource of the translation process. Actions associated with the slides will affect to the global PowerPoint presentation shown to the students, using a connector between them implemented in our application. So the teacher only needs to manage all the class material through the application, using this remote control, also been able to select what has to be translated in each moment.

Text to Sign Language Translator

The following step in the translation process starts with a sentence in Spanish and has to end in a collection of signs to be reproduced by a virtual character in real time. In this step is where the text to sign language translator module must be activated.

This module receives the final Spanish sentence and analyses it so as to generate a correct translation into LSE.

Figure 4. Components included in each module in the Main Application.

This will be later signed by a virtual character in real time. For that translation, two complementary methods are used: a “rule-based method” and an “analogy method”, (Figure 4).

As we will explain later, the system has a vocabulary including specific and general words and several common sentences (obtained by a motion capture system), all of which have been classified into different categories to facilitate the translation.

First of all, each word, from the collection of words provided by the previous modules, is classified into one of the pre-established categories. For example: a sentence like “*IN THE COURSE WE WILL WORK WITH COMPUTER*” will be categorized as “*in<none> the<none> course<object> we<personal pronoun> will<future> work<verb> with<none> computer<objct>*” and translated as “*FUTURE WE COURSE COMPUTER WORK*”.

Next, we apply the “analogy method”, consisting of searching for coincidences with pre-recorded sentences in the vocabulary. If a corresponding sentence is found, it is directly used as the final translation. The sentence will be given to the avatar module which will reproduce the correct associated translation.

In case this method fails, a hierarchical system of rules is applied. As we mentioned before, there is no standard associated to LSE, and, therefore there is no grammatical rules defined that can be applied and codified for translation purposes. In our case, different experts in LSE have extracted a collection of rules that are useful to obtain correct LSE sentences. Using these codified rules, the system tries to find the most adequate one for the sentence being translated, starting from the most particular and moving towards more general ones.

When a coherent rule is found, according to the sentence structure and categories, the module applies it and generates the corresponding translated phrase. After the process, if there is no specific rule to be applied, we have a general case rule at least to try to give the

information to the student. This rule-based methodology allows providing translations of any sentence, giving greater flexibility, only with the limits of the vocabulary available.

When the final sentence is obtained, it must be decomposed into words to be signed. These words pass to the Avatar system module, which will represent them visually.

Avatar System Module

The main functionality of the avatar system module is to represent, control and animate realistically the virtual character integrated in the application so as to reproduce the signs required for the translation of the original sentence.

For this purpose, a vocabulary of around 2,000 words has been captured, for general and specific conversations in the academic area of interest. This vocabulary has a collection of individual signs in the area objective of the final test, and a pool of common vocabulary that can be used for general conversations (like salutations, use of numbers, colours, days, etc.).

Also, the application can spell words using the alphabet for the translations of names, concepts or other required words. To improve and speed the translation, a collection of 150 common sentences in all-purpose and classroom conversations has been included in the vocabulary. This kind of vocabulary is more convenient than those only based on complete sentences. We have more flexibility when translating phrases by using words in the vocabulary. However, it is true that it is more susceptible to translating mistakes or errors due to the non-standard rules used.

Figure 5. Motion Capture Suit and data gloves.

All vocabulary is recorded by an LSE expert using a motion capture system. An 11-infrared cameras setting (NaturalPoint system) and a suit including 34 reflective balls for recording the body motion is used. Also, two data gloves (CyberGlove with 18 sensors) record the movement of all fingers (Figure 5). Each movement captured is adapted to the avatar using MotionBuilder and 3d Studio Max, producing a final version of each sign that has no wrong or missed data. A system based in cal3D and OpenSceneGraph, to integrate, control and animate avatars in real time has been developed. Using this system an avatar can be integrated in the interface, and controlled in RT to simulate the sign language speaking (Figure 6).

Figure 6. Avatar simulating the sign “Navigate”.

Once the final sentence is translated into LSE, the Avatar system receives it as a collection of individual words. This must be reproduced fluently in a smooth and connected way to represent a sentence or as a complete sentence (without any intermediate processing).

In the first case, this module has to obtain the individual signs from the motion database and interpolate them so as to connect and reproduce all the words in the sentence sequentially. Reproducing each sign individually will give the impression of a robotic and non-realistic animation, and may hinder the comprehension by deaf people.

For this reason, the words comprising the sentence are analysed and the best interpolation points between them are determined, based on the main motion curve of the arms (which motion starts and finishes in a pre-established reference position). Next, all the words in the sentence can be reproduced realistically and fluently, applying an interpolation between frames of one sign and the following one.

In the second case, the system receives a complete sentence to be reproduce, obtains it from the database of movements and activates it to be performed by the avatar (without any intermediate processing).

To complete the avatar motion, different automatic facial animations have been created so as to provide a more realistic human aspect.

Communication Module

As we mentioned before, the system presented is based on a client/server architecture, where the main application (server) is in the teacher side, and the client application (one or more) is in the deaf student side. The connection between all the client applications and the server is done using sockets and a collection of messages to send information, control and synchronization data.

The communication module is used in both sides and is involved in the transmission of information between the different systems components. The module is important for several reasons: on the one hand, this module is responsible for sending all the control information between applications.

On the other hand, this module includes the chat that facilitates communication between a teacher and his/her deaf students. The deaf student can send messages in text mode and receives the information in text and LSE format. The teacher sends and receives the information in text mode; this is helpful for people with little or no LSE knowledge.

Figure 7. Teacher interface, with the control of PowerPoint and speech translations.

APPLICATION INTERFACE

The application interface is similar in both sides; it includes specific elements for the teacher to start and manage the PowerPoint presentation directly.

The interface has two modes: PowerPoint (left side) or speak mode (right side). These modes are activated by the teacher (with the remote control) depending on what she/he wants to show to students (Figure 7). As we can see in the figure 7, the interface has a configuration menu at the top, the PowerPoint information in the left side, the avatar visualization and the speak information in the right side and the chat and writing possibilities at the bottom.

The main menu application allows the user to load PPTs and configure different elements of the interface, such as:

- the avatar costume: to adapt it to the final user, making the avatar signing visualization more understandable (Figure 8),
- the background colour: to adequate the background to improve the visualization of the avatar,
- the signing speed: where the user can select between different predefined speeds (0.25x, 0.50x, 1x, 2x, 3x, 4x) to improve their understanding of the lesson,
- the text font: to configure the text in the interface,
- the main signing hand: to adequate the main avatar's hand signing,
- the interface mode: there are two possible modes that the teacher can activate with the remote control: PowerPoint (left side) or speak mode (right side).

In the PowerPoint mode the user is provided with information about the current phrase to be translated, the slide of the presentation, and the translation of the phrase into LSE (Figure 9).

Figure 8. Different customs available for the avatar.

Figure 9. Teacher interface for the PowerPoint translation control.

Figure 10. Teacher interface for the Speech translation control.

Figure 11. Detail of the lower part of the application interface.

In the speaking mode, the user is given information about the original phrase recognized by the Recognizer (over the avatar) and the translation to the LSE (under the avatar), while the avatar is signing (Figure 10).

The lower part of the application has communication facilities (including the chat) and information about the state of the system (Figure 11).

PROBLEMS AND SOLUTIONS

During the development of the application important problems have been found that need to be solved so that the application is successful. Let's review the main problems found and the solution adopted in each case.

First of all, in the Speech Recognizer, where the input information is the teacher voice, it is difficult to determine when a phrase starts and ends. For that reason, after a period of analysis of how people speak and later tests using the recognizer software, we determine that establishing a 1 second of silence between sentences provide a very good results in the recognizer. This method combined with the detection of common connectors in Spanish languages like “y” (and), “o” (or), “pero” (but), etc..., results in a very good obtaining method, being able to separate correctly different phrases in the 90% of the cases.

Moreover, as the LSE language sign is a non-standardized language, to make possible the automatic virtual translation, experts in LSE have extracted a collection of rules to be implemented in the system and apply them to translate the sentences as best as possible. Related with the previous problem, it has been found that the LSE establishes a relation between the words in a sentence that goes from the most general to the most particular. For example, to say “*THE BALL IS IN THE HOUSE*”, they will sign “*HOUSE BALL BE*”, ordering the phrase depending on the size and the particularity of each element. This implies that it is necessary to establish a semantic relation between the different parts of the sentence.

Because we have a very general system, that can be applied to several environments only adding signs to the vocabulary, it is difficult to relation all the words between them to determine which fits in the other. In addition, some of this kind of sentences depends on the context or the meaning of the global sentence, which it is difficult to codify.

For that reason, a property of dimension has been assigned to each word, so the words are ordered in the sentence according to this property.

In the case of the chat system, the main problem found has been that some deaf people cannot write. For that reason, we are now working to improve the chat with pictograms of signs pictures (that can be reproduced to check the sign in case of doubt) organized in different categories. With the pictograms a deaf person can create a sentence to communicate with the teacher, based on the vocabulary we already have. We will develop this extension of the chat and analyse, not only the usability and understanding of the deaf people, but also the comprehension of the teacher, that will receive sentences written with LSE syntax. In the case of the teacher, an extra effort will be needed to understand the global meaning of the sentence, to give a correct answer.

After the evaluation of the application it has been found that not all the deaf people have the same literacy and need the same speed when signing. The same happens with the visual information provided.

For that reason, several customized elements in the interface have been created (see Section 5) to facilitate the deaf people understanding and the teacher usage.

EVALUATION

To evaluate the system and analyse possible problems a complete test with one teacher and a group of deaf people has been performed. The main objective of the session was to obtain a direct feedback from the deaf people about the possibilities and suitability of this tool for helping them in specific courses. The test consisted of a presentation lesson taught by a teacher (with little knowledge of LSE) to a group of deaf people from the Deaf Association of Seville. In a classroom, we try to reproduce the situation where the application will be used later: one teacher with the teacher side application (server) in a laptop, a microphone and the remote control, and a deaf audience, some of them interacting with a laptop with the student application installed. The teacher explained a lesson using a PPT, exchanging between voice and PowerPoint. The audience were able to communicate with her using the chat in the application by means of a laptop available for them. After this test, the deaf people comment their impressions about the application and answered a questionnaire with detailed information about their opinion.

From this test, some ideas were extracted after the revision of the audience opinions and questionnaire results. The results were better than the first impression and the application was improved using the audience suggestions. The main conclusions obtained were:

General Comments

- It is important to be able to select the avatar main hand to sign, because the different signing method of the deaf people, similar to the right-handed or left-handed people. The application was completed to include this possibility (see Section 5).
- The sign language does not have a standard, so different signs are used depending on the area or the city where the application will be used. So, one specific vocabulary can have wrong signs depending on the place where it will be used. This is difficult to resolve in a general way, only the improvement of the vocabulary offered will be possible, also including a classification of the words in Spanish region or area, and selecting it depending on where will the course be teach.
- It is important to take into account the neologism (new words/signs). This involves updating the vocabulary when necessary.
- The deaf people have different literacy levels, so they need to configure the speed of the avatar to their specific skill levels. This was solved, adding to the application the avatar speed configuration (see Section 6).

The problems found in the application by users were:

- Some signs are not clear enough. This problem was corrected after the test improving the signs that were not clear.

- The application had little vocabulary. This problem was later improved with more words and sentences.
- They found few rough movements that need to be smoothening. These movements were improved.
- The avatar has little facial expression and this is important information when the LSE is used. This problem will be improved in the new version of the application.
- They reported some possible problems with the chat, because some of the deaf people cannot write. To solve that, a visual interface will be added to the chat.

At last, the tool presents some advantages and improvements from existing ones:

- From their point of view, it is a very useful system for on-line courses or as a visual book.
- In a short time, they think that this application will be useful to study at home or review material in Spanish, because digital written materials are difficult for them (some of them cannot read). Also, it will be interesting in secondary school classrooms.

In their opinion, it is an incredible system in the area of new technologies, original and it will suppose a big transformation in the training of deaf people, making training and academic courses more accessible for them. The main conclusions obtained were that they considered useful to be able to select the avatar main hand to sign, and the speed of the avatar while signing. Regarding the sign language must be extended with more vocabulary adapted to the specific areas and updated with neologisms. As for the application some signs were not clear enough and had little vocabulary, some movements were rough and needed to be smoothened, and the avatar had little facial expression. Finally, the application can be improve to be used in a short period of time in a concrete scenarios and more widely with several improvements and users tests.

CONCLUSION

In this chapter an automatic Spanish to LSE translator for academic purposes, from voice and PowerPoint data, was explained, reviewing all the application functionality and the results of the test carried out to obtain direct information from deaf people. After the test, the system was completed to incorporate some ideas and solve some problems detailed by the deaf group, but we still have some improvements to be done as future work. It is necessary to improve the avatar facial expression, adding gestures that complete the different signs and make them more understandable. It is important to review the clarity of all the vocabulary, making a deep test with deaf people. The improvement of the chat between teacher and student is been under development, to incorporate a visual interface with signs pictograms and animations in the student side, to facilitate its use by deaf people. After these improvements, a new test will be necessary to check if the system will be useful enough to incorporate it in some specific courses.

ACKNOWLEDGMENTS

The authors would like to thank the Junta de Andalucía for their work and collaboration in the project, to Elena Gándara for her expert collaboration and help in the rules extraction and signs capture, the Deaf Association of Seville for their participation in the test and to all the Artec group from the Robotic's Institute in the University of Valencia for all the development done in this project.

ABSTRACT

We evaluated the perceived communication ability of 25 individuals with chronic traumatic brain injury (TBI) and 25 age-sex-education matched normal controls using an open questions interview format. Each participant completed the interview, which consisted of 21 open questions such as ‘What kind of people are your parents?’ as well as other linguistic and cognitive tests. Using audio recorded versions of the interviews, we rated their answers using the 27 subscales of the La Trobe Communication Questionnaire (LCQ), and evaluated the relationships between LCQ scoring and the other tests. There was a significant difference between participants with and without TBI for 18 of the 27 subscales of the LCQ. As for the 4 factors (Initiation/Conversational flow, Disinhibition/Impulsivity, Conversational Effectiveness, and Partner Sensitivity), the total score for each differed between the 2 groups. Furthermore, LCQ Factor 3 (Conversational Effectiveness) showed a significant correlation with duration of loss of consciousness. No measurements of linguistic and cognitive ability showed a significant relationship with LCQ factor scores. Our findings suggest that communication difficulties can persist for years after injury, which may be relatively independent from other cognitive abilities.

INTRODUCTION

Traumatic brain injury (TBI) including closed head injury (CHI) generally results in some form of verbal communicative deficit. Among the various subtypes of communication disorder, pure aphasia is relatively rare. Many individuals with TBI demonstrate 'subclinical', non-aphasic, or subtle but important communication disorders, which emerge in everyday interpersonal situations [1, 2, 3, 4]. In addition, they may show relatively good formal aphasia test scores with poor communicative success, suggesting problems with the pragmatic and conversational aspects of language usage [3, 5, 6]. In an earlier study, Prigatano et al. described 3 major communication deficits of affected individuals; over-talkativeness, tangentiality, and use of peculiar phraseology [3]. Because of such deficits, they often utilize compensatory strategies while having a conversation [7]. Some with TBI develop speech patterns that are perceived by others as unintelligible, which can impact socialization, vocational outcome, and self-esteem [8].

Conversation is a dynamic and complex activity that requires participants to adhere to certain rules as they interact [9]. As Coelho noted, meaningful participation in a conversation requires that each participant has an ongoing awareness of the other's perspective or needs, and is able to initiate and change topics throughout the interaction, as well as inhibit comments and other behaviors that are inappropriate to the exchange, and continually monitor the overall flow of the conversation [9]. Conversations may be valid for assessing the pragmatic ability of individuals with TBI, as they are considered to be a form of two-way communication [10]. According to Body et al., in spite of terminological variation, 2 main approaches can be discerned from past studies of pragmatic skills in individuals with TBI [6]. The first is a generally applied pragmatic framework taken from a broad range of literature that employs some form of profile or checklist of abilities, while the second approach addresses a specific aspect of interpersonal communication from a pragmatic perspective [6].

Several investigations have been conducted to evaluate the pragmatic and conversational skills of individuals with TBI. For example, topic analysis is sensitive to problems with topic management in those with CHI, indicating that a lack of such abilities may be a core problem of conversation difficulties in individuals who have suffered a brain injury [11]. Coelho et al. noted that subjects with CHI had more difficulty initiating and sustaining conversations than normal controls [12]. In other studies, individuals with TBI seemed less engaged in conversations and more dependent on their partner to sustain the conversational flow [13], and often contributed information that did not facilitate the social interaction [14].

Inappropriate speech rate, i.e., too slowly or quickly, is also an important aspect of conversation. In ratings of verbal and non-verbal behaviors, a CHI group spoke significantly more slowly, less spontaneously, more monotonously, and for shorter durations [15]. Another CHI cohort needed extra time to process questions and formulate an answer [5]. Snow et al. also noted that reduced speed of information may contribute to not only selection, planning, an organization of ideas, but also to efficient auditory processing of the discourse of the conversation partner [16].

Conversation has an interactive nature, thus evaluation of the perceived impression of the conversational partner is important. In a previous study, the CHI group was considered to be less interesting and less likable, and seemed to have a lower level of social skills [15]. Some individuals with TBI seem to have great difficulty meeting the information needs of the

listener or monitoring their own excessive verbal output, and often show little eye contact and pay scant attention to listener feedback or non-verbal cues [8, 17, 18]. Thus, for a conversation partner, communication with individuals with TBI sometimes breaks tacit conversational rules.

As for conversational rules, Grice's conversational principle is a well-known theoretical base used for evaluating the validity of a conversation [19]. Grice contended that conversation is accomplished only by a cooperative effort between participants to achieve transmission of meaning [20] and defined 4 conversational maxims in this co-operative principle; Quantity, Quality, Relation, and Manner. Several measurements have been developed based on Grice's conversational principle, including the La Trobe Communication Questionnaire (LCQ), which has been found to be appropriate for evaluating spontaneous speech of individuals with TBI based on retrospective recall [21] and direct reviews of video recorded sessions [22]. It is also useful for collecting information from various sources including significant others and rehabilitation workers. The LCQ consists of 30 items and utilizes a Likert-type scale with the following possible levels of response for each question; (1) never or rarely, (2) sometimes, (3) often, and (4) usually or always. A higher score indicates increased difficulty with conversation. In terms of factor structure of the LCQ, Douglas et al. proposed a 7-factor model [23]. Thereafter, using a larger sample of individuals with TBI, Struchen et al. proposed a 4-factor model, as follows: Factor 1; Initiation/Conversational flow, Factor 2; Disinhibition/Impulsivity, Factor 3; Conversational Effectiveness, and Factor 4; Partner Sensitivity, which appears to have good face validity [24].

It is important to ask whether a conversational measure is sensitive to distinguish TBI from non-TBI subjects, as well as what components of conversation are perceived to be disordered in individuals with TBI. In a previous study of procedural discourse, the CHI group produced less essential information and relatively more unnecessary information than the non-CHI group [25]. Using the LCQ for measurement, significant differences were seen in 2 previous studies [24, 26]. However, some investigations have failed to distinguish the conversations of TBI individuals from those of normal controls. For example, Snow's analysis of semi-structured interviews between those 2 groups did not distinguish them [27], while Wozniak et al. used intonation unit analysis, but failed to differentiate between TBI and control groups [28].

It remains unclear whether cognitive measurements have relationships with conversational measurements, as the findings of previous studies are controversial. Snow et al. reported that conversational abilities showed moderately significant correlations with word fluency, memory measurement, and the results of Trail Making Test part B [16]. In contrast, McDonald and Pearce found correlations between pragmatic and executive communication ability, while memory measurements yielded no significant correlations [25]. Douglas reviewed studies that explored the associations between executive control processes and pragmatic impairment, and noted that it was surprising to find only relatively weak associations between them [26]. Variability in the measurement tools used may have contributed to these contrasting results.

In the present study, we analyzed audio-recorded interviews from individuals with and without TBI using the LCQ. We then attempted to answer the following questions.

1. Is the LCQ a sensitive conversational measurement tool able to distinguish TBI from non-TBI subjects?
2. What components of conversation are perceived to be disordered in TBI subjects?
3. Do cognitive measurement findings have relationships with conversational measurements?

METHODS

Subjects

The procedures used to recruit the subjects have been reported [29]. Briefly, we enrolled 26 individuals with TBI and 26 non-injured control (NC) individuals for the first stage. Inclusion criteria for the TBI subjects were as follows: (1) coma duration greater than 24 hours (i.e., suggesting severe TBI), (2) cognitive and/or behavioral problems related to TBI, (3) receiving specialized care for TBI, (4) no aphasia and able to talk and communicate with others, and (5) chronic stage of brain injury (>12 months after injury). The subjects in the TBI group were recruited from 6 rehabilitation facilities and 1 self-help group specializing in individuals with TBI (2 private cognitive rehabilitation facilities in Tokyo, 1 sheltered workplace in Kanagawa prefecture, 1 integrated rehabilitation facility in Ibaraki prefecture, 1 hospital outpatient clinic for individuals with brain injuries in Ibaraki prefecture, 1 self-help group for individuals with brain damage in Tokyo). All were given detailed information regarding the present study and provided written informed consent, and each met the criteria. The subjects in the NC group consisted of graduate school students, members of a poetry reading group, members of an orchestra group, and healthy elderly individuals who had registered with an out-placement office for elderly people in Tokyo. Exclusion criteria for the NC group were as follows: (1) past history of receiving psychiatric treatment for schizophrenia or mood disorders (e.g., depression), (2) past history of head injury with loss of consciousness, (3) past history of stroke, and (4) past history of any other disorders of the brain such as brain tumor. Among the 26 subjects in the NC group, 1 reported a past history of brain injury (motor vehicle accident) with loss of consciousness and was excluded, thus the NC group was finally comprised of 25 subjects. For the purpose of education-matching between the groups, the subject in the TBI group with the fewest years of education was excluded from further analysis. Thus, data from 25 individuals with TBI and 25 age-sex-education-matched control subjects were used in the present study.

As shown in Table 1, the mean age in the TBI group was 35.9 years (SD=10.3) and that was 36.6 years (SD=13.1) in the NC group. There were 4 (16%) females in the TBI group and 7 (28%) in the NC group. In the TBI group, the mean age at injury and duration after TBI were 23.8 years (SD=11.4) and 146.4 months (SD=100.8), respectively, while the mean period of unconsciousness was 30.2 days (SD=24.9). Most subjects in the TBI group (21 of 25) had received a brain injury due to a traffic accident.

The protocol of the present study was approved by the institutional review board of the Tsukuba Memorial Hospital Ethics Committee.

Table 1. Subject backgrounds

	TBI (n=25)	NC (n=25)	Statistics (t-test, Chi square test)
Age (SD)	35.9 (10.3)	36.6 (13.1)	n.s.
Sex (M/F)	21/4	18/7	n.s.
Age at time of brain injury (SD)	23.8 (11.4)	-	-
Months since injury(SD)	146.4 (100.8)	-	-
Loss of consciousness (days) (SD) ^a	30.2 (24.9)	-	-
Cause of injury			
Traffic accident	21 (84%)	-	-
Fall	3 (12%)		
Other (e.g., fight)	1 (4%)		
Years of education			
<10	1 (4%)	0 (0%)	n.s.
10-12	9 (36%)	4 (16%)	
13-15	9 (36%)	6 (24%)	
>15	6 (24%)	15 (60%)	

^a The precise number of days was not available for 2 subjects whose time of loss of consciousness was >24 hours.

PROCEDURES

Conversation Task

To examine spontaneous conversation, we conducted a semi-structured interview that consisted of 21 open-question items (Table 2). Most of the questions were regarding autobiographical memories and opinions about daily life. The subjects were interviewed individually in a quiet room and the instructions were given as follows. ‘I will ask you some questions. You can answer with whatever you want to say. Feel free to speak your opinion’. All speech was recorded by a digital audio recorder and later transcribed verbatim. The mean length of the interviews was 917.2 seconds (SD=347.3) in the TBI group and 678.6 seconds (SD=205.1) in the control group. For estimating perceived communication ability, the first author rated 27 of the 30 items of the LCQ while listening to the recorded audio data from each interview. We excluded questions 6 (‘Finds it hard to look at the other speaker’), 13 (‘Finds it hard to follow group conversation’), and 29 (‘Loses track of conversations in noisy places’) from our analysis, because these 3 items could not be examined by using audio data.

As noted above, the LCQ items were graded using a Likert-type scale, with the possible levels of response for each question, as follows: (1) never or rarely, (2) sometimes, (3) often, and (4) usually or always. Higher scores indicated increased difficulty with conversation. We rated each subscale from 1 to 4 based on the perceived frequency of occurrence, and then computed the total score of the 27 LCQ subscales and the sum of the 4 factors suggested by Struchen et al. [24]. Factor 1, Initiation/Conversational flow (questions 2, 5, 7, 8, 14, 16, 18, 26), is related to difficulties with starting and maintaining conversation. Factor 2, Disinhibition/Impulsivity (questions 9, 12, 17, 22, 24, 27), represents impulsive or disinhibited conversational behaviors, such as saying rude things. Factor 3, Conversational

Effectiveness (questions 11, 15, 19, 21, 23, 28), consists of items related to the effectiveness of conversation, such as being accurate and logical in expression, and having the ability to easily change speech style. However, these 6 items require reverse scoring. Factor 4, Partner Sensitivity (questions 3, 4, 10, 25), consists of items related to sensitivity to a conversational partner's needs, such as repeating information, talking about a topic for too long, and switching topics too quickly [24]. We did not include questions 6, 13, and 29 in our analysis, thus the total scores for Factor 1 and 2 might be lower than in other studies.

OTHER LINGUISTIC AND NEUROPSYCHOLOGICAL ANALYSES

All subjects were also administrated a battery of other standardized linguistic and neuropsychological tests aimed to evaluate cognitive competence regarding logical memory, working memory, and executive function.

LINGUISTIC TESTS

To test the relationship between the LCQ measurements and other spontaneous linguistic assessments, the Spontaneous Speech subtest from the Western Aphasia Battery (WAB) was also used [30, 31]. This subtest includes 2 measurements; (A) information content and (B) fluency, grammatical competence, and paraphasia. Both scales were rated from a score of 0 (very severe) to 10 (no problem).

Table 2. Twenty-one interview items used in the present study

- | |
|---|
| <ol style="list-style-type: none"> 1) How are you today? 2) Are you nervous for this interview? 3) What kind of people are your parents? 4) What kind of people are your brothers and sisters? 5) What do you do during the holidays? 6) What skills do you have? 7) When you were an elementary school student, what subject were you good at? 8) When you were an elementary school student, what subject were you bad at? 9) When you were an elementary school student, what was your dream for the future? Also, please tell me the reason. 10) When you were an elementary or middle school student, what club activities did you do? 11) Tell me a happy memory from when you were an elementary school student. 12) What are your strengths? 13) What are your weaknesses? 14) Where do you want to go to travel? Please tell me the reason. 15) What food do you like? Please tell me the reason. 16) Which do you like, dogs or cats? Please tell me the reason. 17) Why do some people believe in God? 18) In Japan, suicide is a matter of concern. What is your opinion about suicide? 19) Please tell your opinion about politics in Japan. 20) What was your experience with this interview? 21) Rate your speech today up to 100 points. |
|---|

The Japanese version of the National Adult Reading Test (JART) was also used to evaluate lexical knowledge for reading ideographic words [32, 33], with the number of correct readings of 50 JART stimuli (possible score 0-50) used for analysis.

MEMORY

Participants were administrated the Orientation, Logical Memory I and II, and Digit Span Forward and Backward subtests from the Wechsler Memory Scale Revised version (WMS-R) [34, 35]. Higher scores indicated higher function for each memory index.

EXECUTIVE FUNCTION

To evaluate executive function, Rule Shift Cards, and Key Search and Temporal Judgment subtests from the Behavioral Assessment of Dysexecutive Syndrome (BADS) [36, 37] were administrated. Each subscale was scored from 0-4 points, with higher scores indicating good performance.

STATISTICAL ANALYSIS

Independent t-tests were used to compare total scores, each item score, each factor score of the LCQ between the groups. To examine the relationships between the score of the LCQ factors and other cognitive measures, Pearson's correlation coefficient was employed. The level of significance was set at $p < 0.05$ (two-tailed test). All statistical analyses were performed using SPSS version 22 for Windows software.

RESULTS

Table 3 shows the mean scores for the TBI and NC groups for total LCQ score and each LCQ item. Independent t-tests revealed a significant difference between the groups for total score and 18 of the 27 subscales of the LCQ. The largest t-value was obtained for Question 10 ('Hesitates, pauses, or repeats him/herself?') ($t = 6.86$, $p < 0.01$).

As shown in Table 4, significant differences between the groups were seen for all 4 factors included in the analysis. For Factor 1 (Initiation/ Conversational flow), the TBI group had a score of 13.20 (SD=2.85) and the NC group 9.12 (SD=0.88) ($t = -6.82$, $p < 0.01$). For Factor 2 (Disinhibition/ Impulsivity), the TBI group had a score of 9.04 (SD=2.70) and the NC group 6.76 (SD=1.45) ($t = -3.72$, $p < 0.01$). For Factor 3 (Conversational Effectiveness), the TBI group had a score of 10.72 (SD=3.00) and the NC group 7.04 (SD=1.27) ($t = -5.63$, $p < 0.01$). For Factor 4 (Partner Sensitivity), the TBI group had a score of 6.72 (SD=1.70) and the NC group 4.64 (SD=0.70) ($t = -5.67$, $p < 0.01$).

Table 3. Mean, standard deviation, and t values for TBI and control subjects for each La Trobe Communication Questionnaire (LCQ) item

Items	TBI (n=25)	NC (n=25)	t value
Total score of LCQ	44.56 (7.20)	30.92 (3.45)	8.54**
1. Leave out important details?	1.92 (0.64)	1.28 (0.46)	4.06**
2. Uses a lot of vague or empty words such as 'you know what I mean' instead of the right word?	1.88 (0.67)	1.08 (0.28)	5.55**
3. Go over and over the same ground in conversation?	1.32 (0.48)	1.00 (0.00)	3.36**
4. Switches to a different topic of conversation too quickly?	1.04 (0.20)	1.04 (0.20)	0.0
5. Needs a long time to think before getting his/her message across?	2.44 (1.00)	1.48 (0.59)	4.13**
6. Finds it hard to look at the other speaker?	NA	NA	NA
7. Has difficulty thinking of the particular word he/she wants?	1.80 (0.71)	1.08 (0.28)	4.74**
8. Speaks too slowly?	1.60 (0.76)	1.08 (0.28)	3.20**
9. Says or does things others might consider rude or embarrassing?	1.28 (0.46)	1.04 (0.20)	2.40*
10. Hesitates, pauses, or repeats him/herself?	2.84 (0.85)	1.48 (0.51)	6.86**
11. Knows when to talk and when to listen?	1.12 (0.44)	1.04 (0.20)	0.83
12. Gets 'side-tracked' by irrelevant parts of the conversation?	1.60 (0.87)	1.08 (0.40)	2.73**
13. Finds it difficult to follow group conversations?	NA	NA	NA
14. Needs the other person to repeat what they have said before being able to answer?	1.36 (0.49)	1.16 (0.37)	1.62
15. Gives people information that is not correct?	1.64 (0.70)	1.12 (0.33)	3.36**
16. Makes a few false starts before getting his/her message across?	1.52 (0.65)	1.04 (0.20)	3.51**
17. Has trouble using his/her tone of voice to get the message across?	1.92 (0.95)	1.04 (0.20)	4.51**
18. Has difficulty getting the conversation started?	1.00 (0.00)	1.00 (0.00)	NA
19. Keeps track of the main details of conversations?	1.48 (0.65)	1.20 (0.41)	1.84
20. Gives answers that are not connected to the question?	1.48 (0.65)	1.00 (0.00)	3.67**
21. Finds it easy to change his/her speech style (e.g., tone of voice, choice of words) according to the situation he/she is in?	2.24 (1.09)	1.20 (0.41)	4.46**
22. Speaks too quickly?	1.12 (0.33)	1.20 (0.65)	-0.55
23. Puts ideas together in a logical way?	2.04 (0.84)	1.16 (0.37)	4.78**
24. Allows people to assume wrong impressions from his/her conversations?	1.84 (0.80)	1.16 (0.37)	3.85**
25. Carries on talking about things for too long in his/her conversations?	1.52 (0.96)	1.12 (0.44)	1.89
26. Has difficulty thinking of things to say to keep the conversation going?	1.60 (0.65)	1.20 (0.41)	2.62*

Items	TBI (n=25)	NC (n=25)	t value
Total score of LCQ	44.56 (7.20)	30.92 (3.45)	8.54**
27. Answers without taking time to think about what the other person has said?	1.28 (0.54)	1.24 (0.52)	0.27
28. Gives information that is completely accurate?	2.24 (0.78)	1.32 (0.48)	5.04**
29. Loses track of conversations in noisy places?	NA	NA	NA
30. Has difficulty bringing the conversation to a close?	1.48 (0.92)	1.08 (0.40)	2.00

Factor 3 (Conversational Effectiveness)	-0.32	-0.34	-0.06
Factor 4 (Partner Sensitivity)	-0.18	-0.03	0.04

^a Note: We excluded questions 6, 13, and 29 from analysis.

Our analysis of background variables (Table 5) showed that age at investigation was significantly related to Factor 4 (Partner Sensitivity) ($r=0.41$, $p<0.05$). Furthermore, months since injury had significant associations with total LCQ score and Factor 4 ($r=0.44$, $p<0.05$, and $r=0.49$, $p<0.05$, respectively), while loss of consciousness had a significant relationship with Factor 3 (Conversational Effectiveness) ($r=0.60$, $p<0.01$).

In the results of the linguistic tests, WAB spontaneous speech subscales A (information content) and B (fluency, grammatical competence, paraphasia), and JART (ability to read Japanese ideographic words) were not significantly related to any of the LCQ factors (Table 6).

As for the other cognitive measurements, no pair showed a significant association. In other words, LCQ total score and the scores for each of the 4 factors had no significant relationship with memory or executive measurements (Table 7).

DISCUSSION

In the present study, individuals with TBI had different results as compared to the NC group for 18 of 27 items and all 4 factors of the LCQ. These results suggest that the LCQ conversational measurement tool is adequately sensitive to distinguish individuals with TBI from those without. Our findings are similar to a previous study in which TBI subjects performed significantly worse than their matched controls on the LCQ [24, 26]. In the present TBI cohort, the total score for the LCQ (44.56) was relatively lower than that in previous studies [21, 23, 24, 26], which may have been related to differences in the items employed. We excluded questions 6, 13, and 29 from analysis, hence the total scores for Factor 1 and 2 were decreased as compared to previous investigations.

The 5 items with higher scores in the TBI subjects were ‘5. Needs a long time to think before getting his/her message across?’, ‘10. Hesitates, pauses or repeats him/herself?’, ‘21. Finds it easy to change his/her speech style (e.g., tone of voice, choice of words) according to the situation he/she is in?’), ‘23. Puts ideas together in a logical way?’, and ‘28. Gives information that is completely accurate?’. Three of those (nos. 5, 10, 21) were also included in the top-10 frequency of difficulty ranking of Douglas [26], while numbers 5 and 10 belong to the Gricean manner domain. The largest difference was observed for Factor 1 (Initiation/Conversational flow), which is comprised of items related to difficulties with starting and maintaining conversations [24]. A higher score for that factor might be related to slowness, and use of vague or empty words. This result suggests that the most critical characteristic of conversation in individuals with TBI is a deficit of the ‘manner’ domain. This finding is also in accord with some previous studies. For example, individuals with brain injury were reported to require extra time to process a conversation [15]. Also, Penn and Cleary noted that TBI subjects used a wide range of compensatory strategies, including self-repetition, revision, and pausing [7]. In addition to narrative discourse [29], ‘time’ seems to be an important factor in conversations with individuals with TBI.

In the present study, the frequency of 2 items, i.e., ‘23. Puts ideas together in a logical way?’ and ‘28. Gives information that is completely accurate?’ were greater (i.e., worse score) than in the study of Douglas [26]. In contrast, 2 other items, ‘12. Gets “side-tracked” by irrelevant parts of the conversation?’ and ‘19. Keeps track of the main details of conversations?’ were not as high as compared to that study. These differences might be due to the different conversation tasks employed, as we used semi-structured interview data for assessment, whereas Douglas used daily conversation for evaluating with the LCQ. The semi-structured interview method requires higher levels of accuracy and logicity in spontaneous speech as compared to daily talk, and such a framework may make it easier for individuals with TBI to keep track of the main topics as compared to daily free conversation. Thus, the difference between our results and those of Douglas might be explained by these situational differences.

Our findings showed that months since injury had a significant correlation with total score for the LCQ and Factor 4 (Partner Sensitivity). Interestingly, conversational deficits increased with longer periods of time since the injury. This result seems unusual, because it is natural to anticipate that deficits in conversation would recover over the course of time. However, in our subjects with TBI, conversational deficits did not show such a natural recovery. Similar results were presented in a previous study, in which the conversational abilities of the TBI subject group, as measured by Clinical Discourse Analysis, did not improve over time [16]. Rousseaux et al. also concluded that communication disorders remain long after TBI [38].

Factor 3 (Conversational Effectiveness) showed a strong association with the length of loss of consciousness in the present study. That factor consists of items related to the effectiveness of conversation, such as being accurate and logical in expression, and having an ability to easily change speech style [24]. Therefore, logicity and accuracy in conversation may be vulnerable to brain injury.

Table 7. Pearson correlation coefficients for LCQ factors, memory, and executive function in TBI subjects (n=25)

	WMS-R					BADs		
	Orientation	Logical Memory I	Logical Memory II	Digit Span Forward	Digit Span Backward	Rule Shift Cards	Key Search	Temporal Judgment
Total score ^a	-0.22	-0.23	-0.21	0.18	-0.18	-0.36	-0.37	-0.10
Factor 1 (Initiation/Conversational flow)	0.00	-0.15	-0.24	-0.11	-0.21	-0.10	-0.26	-0.03
Factor 2 (Disinhibition/Impulsivity)	-0.14	-0.11	-0.03	0.27	0.07	-0.38	-0.16	0.13
Factor 3 (Conversational Effectiveness)	-0.33	-0.31	-0.33	0.26	-0.26	-0.35	-0.03	-0.17
Factor 4 (Partner Sensitivity)	0.06	0.05	0.08	0.02	-0.04	-0.08	-0.08	-0.02

^a Note: We excluded questions 6, 13, and 29 from analysis.

In terms of our third question, the relationships between conversational variables and cognitive measurements were shown to be weak based on our data. Namely, WAB spontaneous speech subtests, ability to read ideographic words, memory scale score, and scores for executive function were not significantly related to any factor of the LCQ. These results differed from those of Douglas [26], who found significant relationships between LCQ scores and executive function measured by an FAS verbal fluency task. This inconsistency could be explained by the differences in measurements of executive function. We employed 3 subtests of BADs for evaluating executive function. In contrast, an FAS verbal fluency task requires word retrieval skill. It seems plausible that FAS measurement results have a significant relationship to conversational competency, because the FAS may reflect verbal ability. Further detailed analysis is needed.

Conversation ability may be affected by other factors not examined in the present study. In recent reports, the importance of environmental factors, such as encouraging relationships with communication partners or empowering situations, have been recognized [10, 39, 40, 41, 42]. Togher et al. noted that the same subjects will show widely different communication behaviors according to whom they are interacting with [39], thus the conversation partner is important when evaluating everyday conversation [43]. Similarly, Kilov et al. found that empowering contexts (equal distance, knowledge) and meaningful interactions may reduce the necessity for additional prompting to sustain the flow of natural discourse, and affected individuals may eventually be able to show competence [44]. In the present study, the examiner unilaterally questioned the individuals with TBI and listened to their answers. This asymmetrical structure might have affected the quality of speech of our TBI subjects. Moreover, as McHenry and Wilson stated, psychosocial variables are also contributors to unintelligible speech [8]. Their case study illustrated that progress is impacted by pre-morbid personality, physiological status, cognitive deficits, and psychosocial history.

LIMITATIONS

Our study has some limitations. The validity and reliability of the Japanese version of the LCQ has not been confirmed. Since only a single examiner (first author) who was not blind to diagnostic information for the subjects rated the questionnaire, the results may be biased. Further examinations to develop the validity and reliability of the Japanese version of the LCQ are needed.

CONCLUSION

We evaluated the perceived communication ability of individuals with chronic TBI using an open questions interview format with 27 subscales of the LCQ and recorded audio from the interviews. We found a significant difference between participants with and without TBI for 18 of the 27 subscales in the questionnaire. As for the LCQ factors, the total score for all 4 (Initiation/Conversational flow, Disinhibition/Impulsivity, Conversational Effectiveness, Partner Sensitivity) differed between the groups. Furthermore, no other measurements of linguistic and cognitive ability showed a significant relationship with the LCQ factor scores. Our results suggest that communication difficulties persist for years after injury in affected individuals, while conversation seems to be relatively independent from other cognitive abilities.

Chapter 10

**ANALYSIS OF NONVERBAL BEHAVIOR IN
AFFECTIVE DISORDERS IN CHILDREN AND
ADOLESCENTS WITH TYPE 1 DIABETES**

***Oleg A. Gilburd, Jana V. Girsh
and Nadezhda A. Donnikova****

Surgut State University, Khanty-Ugra Medical, Surgut, Russia
Institute, Department of Pediatrics, Surgut, Russia

ABSTRACT

The study of nonverbal behavior is important in objectifying and verifying the diagnosis of mental disorders. Also it is important in establishing correct diagnosis of affective disorders (anxiety and depression) in patients with type 1 diabetes using clinical and ethological methods. Ethological analysis of the behavior of children and adolescents with diabetes was conducted using adapted to the objectives of the study “Glossary of nonverbal human behavior”, which includes basic units, simple and complex forms of behavior, as well as their dynamics. Formalization of the severity of behavioral symptoms was carried out in accordance with the scale of human ethological features (Human Ethological Signs Scale, HESS), which provides a 7-point score for ethological expression. We have revealed and ranged several nonverbal patterns recorded with a frequency of more than 90%, which were of particular importance for ethological verification of anxiety in children and adolescents suffering from diabetes. Our results show that ethological analysis of nonverbal behavior in children and adolescents with type 1 diabetes significantly increases the information content of the clinical examination, contributes to objectification and verification of clinical and psychopathological data concerning the presence and severity of affective disorders caused by diabetes and allows one to confidently discriminate between depressive and anxiety disorders in the absence or even loss of verbal contact with the patient.

INTRODUCTION

Nonverbal behavior (NVB) is a system of communication signals recorded in addition to verbal symbols in the visual, auditory, olfactory and tactile channels of information. According to the principles of ethology, NVB of all living creatures including humans, is the language of communication by which true intentions, desires, emotions are translated and perceived. That means the behavior always has a context and is filled with meaning and purpose.

NVB in humans allows one to send and receive from 65% to 80% of useful information within the individual and social communication areas. NVB features analysis provides description and interpretation of how a person moves, what are his gestures, facial expressions and poses in a particular environmental setting. Physiological systems based on their genotypes establish the projected internal scheme of NVB including an instinctive activity. Physiological and behavioral phenotypes are formed in the process of individual human development. The ratio of nonverbal versus verbal communication components in adult person at glance is shifted in favor of the latter, whereas NVB in children plays a major role in interpersonal communication.

NVB studies have objectifying and verifying values in mental disorders diagnostics, and often changes in NVB patterns precede clinical manifestation of the disease. NVB ethological analysis in patients with mental disorders is structured according to the system of behavior levels (Kornetov A.N.):

- 1) elementary behavioral units or motor act units – posture, facial elements, positions and movements of the hands, shoulders, torso, head, legs, nonverbal paralinguistic and prosodic speech components;
- 2) simple behavioral complexes – individual distance, orientation during contact, facial complexes, eye contact, gesture, motor skills of head, shoulders, torso, motor activities of grooming and manipulation;
- 3) sophisticated or contextual behavioral sets – sleep, locomotion, maintenance of body and clothing cleanness, comfortable / agonistic / territorial / migratory / simulation / feeding / dominance / search and exploratory / attention and contact behavior, demonstration of trust and submission.

Play as a sophisticated NVB form has gained importance in our study. Play behavior of children and adolescents had been evaluated during the “Diabetes School” training program and events dedicated to “Diabetes Day”.

Conditions for the assessment of NVB features were the same for all patients (physician’s office). The average length of ethological observation was 20-30 minutes. Single frame analysis of video-recorded behavior displays was performed for each observation.

MATERIALS AND METHODS

All children with type 1 diabetes included in the study were divided into two subgroups depending on the disease duration. The first subgroup was composed of 60 patients with

diabetes lasting of more than three years, whereas 27 children and adolescents with diabetes just manifested or lasting less than one year have formed the second subgroup.

Patients from both subgroups were matched for age and sex. All children were treated predominantly with basal and ultrashort insulin analogs acting in mode of intensified insulin therapy.

The study was carried out with the informed consent of the parents, in accordance with the ethical standards of Helsinki Declaration and Good Clinical Practice for Russian Federation, approved by the Ministry of Health.

Research methods included anamnestic method (life and disease anamneses, maternal history peculiarities), physical examination, laboratory and instrumental studies (glycemic profile, continuous glucose monitoring system CGMS Gold (Medtronic MiniMed, US).

Verification of anxiety and depression conditions during the study was performed with adapted to child's age Spielberger's State-Trait Anxiety Inventory (STAI) and Zung Self-Rating Depression Scale (SDS) with further diagnostics refinement using basic clinical psychopathological method. Anxiety was revealed in 63.3 % (1st subgroup) and 59.3 % (2nd subgroup) of studied children and adolescents, whereas depression was diagnosed in 45.0 % (1st subgroup) and 55.6 % (2nd subgroup), respectively.

Evaluation of nonverbal behavior of children and adolescents from both groups was performed using particularly adapted to the study objectives "Glossary of Nonverbal Human Behavior" which included information for elementary units, simple and complex forms of behavior, and their dynamics (Samohvalov V.P.; Eibl-Eibesfeldt I).

Formalization of behavioral traits degree was carried out in accordance with the Human Ethological Signs Scale (HESS) (Gilburd O.A.), which provided a 7-point ethological expression assessment. Normal behavioral sign expression was correspondent to 1 – 3 points, whereas 4 – 7 points were marking the presence of varying severity affective disorders.

NONVERBAL BEHAVIOR OF CHILDREN AND ADOLESCENTS WITH ANXIETY CAUSED BY TYPE 1 DIABETES

Nonverbal behavior of all children and adolescents with type 1 diabetes accompanied by anxiety disorders was characterized by the following features (Tables 1, 2):

- among registered elementary behavioral units we have observed: eyes running around and unblinking (fixed) gaze, lower lip trembling, tight / tucked lips, fixing both hands on an object (like a chair, etc.) or under the patient's armpits, one hand clenching other hand fingers, hand stroking another hand, raised shoulders, tense and periodically accelerated speech, voice tremor;
- among simple behavioral complexes there were detected: intense facial expressions of anxiety, expectation, alertness; facial expressions with a high mobility of eyebrows; a gesture of latent anxiety (a hand rubbing one's neck while stretching it); individual distance increase at the beginning of conversation followed by distance decrease at the conversation end; half-turned orientation during contact; head shaking or rocking; shoulders reaction (arms lifting while head lowering as a sign of fear or element of hiding); jumps at the sudden stimulus; jactation (body-rocking); intensive

auto-grooming (bringing oneself up, preening, correcting clothes, smoothing one's hairs, brushing from one's shoulders, rubbing one's face); intensive manipulation with an external object or with body part (earlobe, hairs), or with clothing; playing with fingers; biting lips (labiophagy);

- in the dynamics of both elementary units and simple behavioral complexes we have noted: restlessness in the form of polymorphic stereotypes of facial expressions, posture (jactation), head (nodding, rocking), hands (stroking, rubbing, playing with fingers, palpation); manipulation; gestures; grooming; motor acts of shoulders, feet (shuffling, blows with toe and heel, etc.); nonverbal speech components;
- in cases of sophisticated behavioral sets we have observed: intermittent sleep with frequent change of positions and early awakening; manipulation with food, licking, swallowing, oral motions without speech, indiscriminate eating habits, changes in meal schedule; looking around, neophobia as exploratory behavior features; cautious visiting of the physician's office, shuttle movements within area borders as features of territorial behavior.

The frequency of registered cases and the degree of expression of anxiety ethological signs based on a 7-point HESS scale for both subgroup of children and adolescents are presented in Tables 1, 2. Analysis of the Tables data shows that basic values in the subgroup of patients with type 1 diabetes lasting more than three years, i.e., the average frequency of registration of full ethological repertoire (80.6%) and the average degree of nonverbal signs of depression severity (5.49 ± 0.27) are higher than in the subgroup of patients with diabetes manifesting or lasting less than one year (74.4% and 3.81 ± 0.76 , respectively).

This means that nonverbal *anxiety* manifestations in chronically ill children and adolescents with diabetes are more diverse and more clearly marked than that of children with recently diagnosed disease.

Nonverbal patterns recorded at a frequency of more than 90% are of particular importance to ethological verification of anxiety in children and adolescents long suffering from diabetes. Among them to note are eyes running around, tucked lips, raised shoulders, tense and periodically accelerated speech, tense facial expressions of anxiety and expectation, latent anxiety gesture, jumps at the sudden stimulus; labiophagy in feeding behavior; food manipulation and licking, indiscriminate eating habits, changes in meal schedule; looking around and neophobia in exploratory behavior. In contrast, according to our data the most important nonverbal anxiety markers in children and adolescents with diabetes lasting less than a year were: tense and periodically accelerated speech, voice tremor, facial expressions with a high mobility of eyebrows, playing with fingers, and cautious visiting of the physician's office. In seven children and adolescents in the control group (14.8%) with anxiety revealed as a diseased state we have observed the same nonverbal signs with an average frequency of the full ethological repertoire (50.8%) and the average severity of 3.2 ± 0.57 points, which corresponds to moderate anxiety based on HESS evaluation. These figures generally comply with values ranging between health and slight pathology.

Children and adolescents from both studied groups without any marks of affective disorders revealed nonverbal signs of depression with an average frequency of 8.9% and median expression of 2.1 ± 0.2 points, which corresponds to the level of normal situational transitory reactions.

Table 1. The frequency and intensity of HESS-signs of anxiety in the 1st subgroup (n = 38)

Ethologic pattern	HESS-signs frequency		HESS signs intensity score
	abs.	%	Mean $\pm$ SD
Elementary Behavioral Units			
Eyes running around	38	100	6.00 $\pm$ 0.22
Unblinking (fixed) gaze	18	47.3	4.48 $\pm$ 0.19
Lower lip trembling	15	39.4	5.64 $\pm$ 0.33
Tight lips	29	76.3	5.80 $\pm$ 0.24
Tucked lips	35	92.1	4.92 $\pm$ 0.28
Hands fixing on object /armpits	26	68.4	5.68 $\pm$ 0.44
Hand fingers clenching	23	60.5	5.17 $\pm$ 0.34
Hand stroking hand	25	65.7	5.90 $\pm$ 0.26
Raised shoulders	38	100	5.12 $\pm$ 0.24
Periodically accelerated tense speech	38	100	6.01 $\pm$ 0.20
Voice tremor	28	73.7	6.14 $\pm$ 0.16
Simple behavioral complexes			
Intense facial expressions of anxiety, expectation, alertness	38	100	6.20 $\pm$ 0.30
High mobility of eyebrows	27	71.1	5.75 $\pm$ 0.26
Latent anxiety gesture	38	100	6.19 $\pm$ 0.18
Individual distance change	38	100	4.86 $\pm$ 0.24
Half-turned orientation	32	84.2	4.65 $\pm$ 0.40
Head shaking or rocking	17	44.7	5.83 $\pm$ 0.28
Shoulders reaction	33	86.8	5.68 $\pm$ 0.24
Sudden stimulus jumps	38	100	6.18 $\pm$ 0.32
Jactation	33	86.8	5.80 $\pm$ 0.28
Intensive auto-grooming	38	100	5.61 $\pm$ 0.26
Intensive object manipulation	15	39.5	5.47 $\pm$ 0.34
Playing with fingers	32	84.2	4.66 $\pm$ 0.30
Labiophagy	37	97.3	5.60 $\pm$ 0.21
Polymorphic stereotypes	34	94.4	5.22 $\pm$ 0.55
Sophisticated Behavioral Sets			
Intermittent sleep with frequent change of positions and early awakening	28	87.5	6.12 $\pm$ 0.18
Nutritional behavior: food manipulation, licking, swallowing, oral motions without speech, indiscriminate eating habits, changes in meal schedule	37	97.3	5.42 $\pm$ 0.22
Exploratory behavior: looking around, neophobia	38	100	4.61 $\pm$ 0.29
Territorial behavior: cautious visiting of the physician's office, shuttle movements within area borders	36	94.7	4.47 $\pm$ 0.18
Average frequency of registered events and expression of the full repertoire of ANXIETY ethological repertoire in the 1 st subgroup		80,6%	5,49 $\pm$ 0,27

NONVERBAL BEHAVIOR OF CHILDREN AND ADOLESCENTS WITH DEPRESSION CAUSED BY TYPE 1 DIABETES

Nonverbal behavior of all diabetic children and adolescents from the main subgroup accompanied by depressive syndrome was characterized by the following features:

- in the registry of elementary behavioral units we have observed: avoiding eye contact, looking out the window or viewing of hands, inflating cheeks and lips, drooping mouth corners, raised inner edge of eyebrows, horizontal forehead wrinkles (with Veraguth's fold as optional feature found only in adolescents); lustreless eyes; transient elements – tears, crying facial expressions, submissive gestures (palm pressed to one's chest with a slight bow and head nod); hiding (covering) of one's groin with hands; standing and sitting postures with head down, hands wound back; crossed legs as groin hiding element; tendency to knee bending and further head lowering in standing position; quiet voice of low tone in nonverbal speech components, increased speech pauses during verbal contact as evidence of proximity of hidden (dissimulated) information and intentions; propensity to vowels stretching, increasing number of speech errors and verbal stereotypes throughout the contact;
- in the simple behavioral complexes registry there have been observed bias to increase individual distance, reduction of greetings complex, body orientation during interview similar to *phototaxis* (i.e., contact avoidance accompanied by turning aside to light source), auto-aggressive forms of auto-grooming, onychophagia and trichotillomania;
- in the registry of complex behavioral sets we have revealed inversion of "sleep – wake" rhythm; fetal sleep position; slow motion walking while preserving key elements of submissive posture; deactualization of hygienic, comfortable and search (research) behavior; actualization of imitative behavior in adolescents with increased risk of developing Werther syndrome (copycat suicide); anorexia in eating behavior; reduction in dominance within individual and subgroup territory; neglecting family roles, reduction of gaming activity.

During actualization of suicidal tendency in adolescents we have observed that signs of submission and obedience within elementary units of posture, gesture, facial expressions in simple and sophisticated behavioral sets were superseded with severe, persistent and prevalent signs of avoiding any form of contact (from ocular up to bodily) with others.

Also, their exploratory behavior was reduced to finding suitable area and methods for convenient implementation of auto-aggressive intentions.

The frequency of registration and expression of ethological signs of depression on a 7-point scale HESS in children and adolescents of both subgroups are presented in Tables 3, 4.

Analysis of these tables shows that in the subgroup of patients with diabetes experienced more than 3 years the average frequency of registration of full ethological repertoire (86.6%) and the average severity of nonverbal signs of depression (5.42 ± 0.29) are considerably higher than those among patients with manifesting diabetes manifesting or lasting less than one year (76.4% and 4.63 ± 0.58 , respectively).

Table 3. The frequency and intensity of HESS-signs of depression in the 1st subgroup (n = 27)

Ethologic pattern	HESS-signs frequency		HESS signs intensity score
	abs.	%	Mean ± SD
<i>Elementary Behavioral Units:</i>			
Eye contact avoidance	27	100	5.54 ±0.21
Looking out the window or viewing of hands	27	100	5.77±0.33
Inflating cheeks and lips	24	88.9	5.19±0.24
Drooping mouth corners	25	92.5	5.32±0.66
Sad or frowning eyebrows	22	81.5	4.51±0.52
Raised inner edge of eyebrows	22	81.5	4.19±0.28
Horizontal forehead wrinkles	21	77.8	4.22±0.31
Veraguth's fold (optional in adolescents)	11	41	5.88±0.22

Shoulder lessening	18	66.7	6.06±0.21
Crossed legs as groin hiding element	27	100	5.88±0.33
Tendency to knee bending and further head lowering in standing position	27	100	5.72±0.18
<i>In nonverbal speech components:</i>			
Quiet voice	27	100	5.52±0.29
Low tone	22	81.5	4.21±0.45
Increased speech pauses	27	100	6.11±0.12
Propensity to vowels stretching	24	88.9	4.33±0.24
Increasing number of speech errors	26	94.7	5.91±0.17
Increasing number of verbal stereotypes	27	100	5.90±0.35
<i>Simple behavioral complexes:</i>			
Bias to increase individual distance	27	100	6.09±0.14
Reduction of greetings complex	27	100	5.11±0.49
Phototaxis-like body orientation	27	100	6.11±0.24
Auto-aggressive forms of auto-grooming	21	77.8	5.29±0.42
<i>Sophisticated Behavioral Sets:</i>			
Insomnia, "sleep – wake" rhythm inversion, fetal sleep position	27	100	6.22±0.25
Slow motion walking with preserved submissive posture elements	27	100	5.90±0.19
Deactualization of hygienic, comfortable and search (research) behavior	24	88.9	5.16±0.62
Actualization of imitative behavior with risk of Werther syndrome (adolescents only)	15	55.6	5.88±0.26
Anorexia	16	59.2	4.45±0.21
Dominance reduction within individual and subgroup territory	27	100	6.08±0.11
Neglecting family roles	27	100	5.82±0.19
Reduction of gaming activity	24	100	4.87±0.09
Average frequency of registered events and expression of the full repertoire of DEPRESSION ethological repertoire in the 1 st subgroup	86.60%		5.42±0.29

Table 4. The frequency and intensity of HESS-signs of depression in the 2nd subgroup (n = 15)

Ethologic pattern	HESS-signs frequency		HESS signs intensity score
	abs.	%	Mean ± SD
<i>Elementary Behavioral Units:</i>			
Eye contact avoidance	11	73.3	4.30±0.32
Looking out the window or viewing of hands	12	80	4.20±0.68
Inflating cheeks and lips	12	80	4.33±0.45
Drooping mouth corners	13	86.7	4.31±0.69
Sad or frowning eyebrows	10	66.7	4.30±0.45
Raised inner edge of eyebrows	10	66.7	4.10±0.67
Horizontal forehead wrinkles	11	73.3	4.01±0.60
Veraguth's fold (optional in adolescents)	3	20	4.67±0.33
Lustreless eyes	12	80	4.33±0.76
Tears, crying facial expressions	10	66.7	4.10±0.71
Submissive gestures	13	86.7	4.60±0.87
Groin hiding (covering)	11	73.3	4.73±0.48
<i>In standing / sitting postures:</i>			
Head down	13	86.7	4.07±0.68
Hands wound back	11	73.3	4.54±0.45
Shoulder lessening	14	93.3	4.86±0.71
Crossed legs as groin hiding element	15	100	5.20±0.73
Tendency to knee bending and further head lowering in standing position	12	80	4.67±0.89
<i>In nonverbal speech components:</i>			
Quiet voice	14	93.3	5.13±0.71
Low tone	9	60	4.08±0.74
Increased speech pauses	15	100	5.20±0.73
Propensity to vowels stretching	12	80	4.42±0.53
Increasing number of speech errors	14	93.3	4.93±0.57
Increasing number of verbal stereotypes	15	100	4.63±0.69
<i>Simple behavioral complexes:</i>			
Bias to increase individual distance	11	73.3	5.67±0.89
Reduction of greetings complex	10	66.7	4.80±0.87
Phototaxis-like body orientation	12	80	5.47±0.71
Auto-aggressive forms of auto-grooming	9	68.4	4.04±0.53
<i>Sophisticated Behavioral Sets:</i>			
Insomnia, "sleep – wake" rhythm inversion, fetal sleep position	13	86.7	5.27±0.76
Slow motion walking with preserved submissive posture elements	15	100	4.73±0.75
Deactualization of hygienic, comfortable and search (research) behavior	12	80	4.33±0.78
Actualization of imitative behavior with risk of Werther syndrome (adolescents only)	3	20	4.67±0.33
Anorexia	6	40	4.92±0.93
Dominance reduction within individual and subgroup territory	11	73.3	5.07±0.69
Neglecting family roles	11	73.3	4.67±0.98
Reduction of gaming activity	15	100	6.01±0.31
Average frequency of registered events and expression of the full repertoire of DEPRESSION ethological repertoire in the 2 nd subgroup	76.4 %		4.63±0.58

This means that nonverbal *depression* manifestations in chronically ill children and adolescents with diabetes are more diverse and more clearly marked than that of children with recently diagnosed disease.

Therefore ethological parameters of depression associated with type 1 diabetes are identical to clinical and psychopathological characteristics of anxiety outlined above.

Nonverbal patterns recorded at a frequency of more than 90% are of particular importance to ethological verification of depression in children and adolescents long suffering from diabetes. Among them to note are avoiding eye contact, looking out the window or viewing of hands, inflating cheeks and lips, drooping mouth corners, lustreless eyes, submissive gestures, covering of one's groin with hands, tendency to knee bending and further head lowering in standing position, quiet voice, increasing of speech pauses, errors, verbal stereotypes, bias to individual distance increasing, reduction of greetings complex, body orientation during interview similar to phototaxis, insomnia, inversion of "sleep – wake" rhythm; fetal sleep position; slow motion walking while preserving key elements of submissive posture, reduction in dominance within individual and subgroup territory, neglecting family roles, refusal of gaming activity.

In turn, among the most important nonverbal markers of depression in children and adolescents with recently diagnosed type 1 diabetes lasting up to one year, we have observed: reduction of the shoulder, crossed legs as part of hiding one's groin, quiet voice, increasing speech pauses, errors, verbal stereotypes, slow motion walking while preserving key elements of submissive posture, refusal of gaming activity. We have observed the same nonverbal features in six (12.8 %) children and adolescents from the control subgroup with clinically revealed light depression. The average frequency of the full repertoire was 71.4 %, with average severity score of 4.08 ± 0.11 points, thus corresponding to "middle" level of HESS. Depressive nonverbal signs in children and adolescents from both groups with no affective disorders were registered with average frequency of 9.4 % (mean expression 2.02 ± 0.13 points), which corresponds to the level of normal situational transient responses.

In general, these results show that ethological analysis of nonverbal behavior in children and adolescents with type 1 diabetes: (1) significantly increases the information content of the clinical patient examination; (2) contributes to objectification and verification of clinical and psychopathological data concerning the presence and severity of affective disorders caused by diabetes; (3) allows one to confidently discriminate between depressive and anxiety disorders in the absence or difficulty of verbal contact with the patient.

Chapter 11

**ESTABLISHING GRAMMATICAL COHESION
IN KENYAN SIGN LANGUAGE (KSL)
FORMAL DISCOURSE:
THE CASE OF A SERMON DELIVERED IN KSL**

Jefwa G. Mweri*, PhD

Department of Kiswahili,
Kenyan Sign Language Research Project
Faculty of Arts University of Nairobi, Nairobi, Kenya

Cohesion: it is the first standard of textuality; it refers to the surface relations between the sentences that create a text i.e., to create connected sentences within a sequence. The formal surface of the text components works according to grammatical forms and conventions. It helps the reader/hearer to sort out the meaning and uses. (Besma, Azzouz (2009)).

ABSTRACT

Religious beliefs can be expressed in distinct language varieties – one such variety is the language of the sermon which Crystal and Davy (1969) say, “Has more in common, stylistically with other forms of public speaking.” Being a form of moral statement aimed at dictating a certain kind of behavior through such strategies as stories, or examples, a sermon’s manner of presentation is formal. This paper focuses on how content is structured in formal KSL discourse – a sermon. It focuses on grammatical cohesion. Grammatical cohesion is about how content is structured through textual features that link episodes together in discourse. In discourse, there are elements that are not part of the content but they help in guiding the reader/listener to interpret information. The flow of the topic can therefore be understood through guidance from structural organization, or through cohesive devices. The structuring of content in discourse through the use of structural devices or linguistic features that mark transition help in establishing cohesion.

This paper is concerned with how cohesion is established in a KSL sermon through reference, substitution, ellipsis, discourse markers and conjunctions.

1. INTRODUCTION

According to Jacobs (2012), a sermon is a form of a lecture or discourse given for the purpose of providing religious instruction or inculcating moral behavior. Usually doing this using a text (or texts) from Sacred Scripture and Church teaching as a point of departure, a sermon directly addresses human conduct from a Judaeo-Christian and Roman Catholic perspective with the explicit intent to either exhort or to rebuke the people seated in the congregation. The goal of a sermon is to get the people in the congregation to change their moral behavior.

The Longman Dictionary of Contemporary English defines a sermon as a religious talk given as part of a Christian church service usually based on a verse from a Bible. The *Collins Concise Dictionary* on its part defines a sermon as an address of religious instruction or exhortation often based on a passage from the Bible especially delivered during a church service.

The definitions above clearly mark out a sermon as part of a church service. Our analysis therefore is not of the full church service but of the sermon delivered in KSL. The sermon under study took about one hour including the dramatization that preceded it.

A sermon's manner of presentation is formal. This formality in manner of presentation is a reflection of the relationship that exists between the minister or preacher and his congregation. Notably also, is the fact that these religious statements based on a particular moral or spiritual view of the word (sermon) can be written as speeches and delivered to a congregation or they may be spoken spontaneously and be given as an extemporaneous sermon. The sermon under analysis was a spontaneous one. Since no notes were used during this particular sermon, it can thus be classified as a textual sermon – that is one that limits itself to one certain thought or a topic suggested by particular scripture text. In this case the topic being the times of Jesus Christ - that is his birth, crucifixion and resurrection. This sermon under analysis also uses other means such as drama to visually depict the theme or point of the sermon; thus it can also be viewed as an illustrated sermon. In this paper, we view a sermon as a speech event in a particular social. The setting for the sermon under analysis is the church hall.

Kenyan deaf people have a unique way of conducting a church service especially in as far as the sermon is concerned. The sermon under analysis is divided into three distinct parts:

- The pre-sermon exposé (prologue)
- A play which solidifies the pre-sermon exposé
- The sermon itself.

A different person from the one who conducts the sermon conducts what we have called the pre-sermon exposé.

Following Cook (1975), the pre-sermon exposé (prologue) mentioned above can be divided into the following episodes:

- An obligatory focal episode (introduction)
- An obligatory developmental episode
- An obligatory closing episode.

The obligatory focal episode talks about the arrest of Jesus and the suffering he went through. The developmental episode focuses on the crucifixion of Jesus. The play, which comes immediately after the prologue is a dramatization of what has been talked about in the prologue or pre-sermon exposé.

The sermon itself can be analyzed structurally as follows:

The death of different prophets before Jesus, the birth of Jesus, the life and times of Jesus, his resurrection and the importance of his resurrection to salvation.

Though we are aware that flow of the topic can be understood through guidance from structural organization, this analysis however focuses on how content is structured through textual features that link episodes together in discourse.

Discourse analysis examines the highest-level units of meaning – and transitions that occur between them in a larger context. “It is a linguistically sensitive and holistic way of reading texts as communicative acts” Streett (2001). In discourse, there are elements that are not part of the content but they help in guiding the reader/listener to interpret information. The structuring of content in discourse through the use of structural devices or linguistic features that mark transition help in establishing cohesion. However, where content is structured in such a way that no overt features are used but continuity of meaning can help readers or listeners discern the transition, coherence on the other hand is established.

The sermon as indicated earlier was delivered in Kenyan Sign Language (KSL). Kenyan Sign Language, can be defined as a patterned visual gesture language used by people who are deaf (and hearing people who have learnt it) for communication. People who are deaf in Kenya are members of the Deaf culture and are therefore users of a different language from that of the dominant hearing culture. This makes sense when one thinks of language as consisting of a system of conventional and arbitrary symbols (audio or visual) determined by a culture. Samovar et al. (2006). Thus different cultures evolve different languages. In the culture of spoken language words are used and in the culture of people who are deaf, signs are used. A person who is deaf cannot make use of the vocal - auditory channel (used by the majority) for communication. However, as Yule (2006) points out: “... the use of the vocal-auditory channel is certainly not a defining feature of human language.”

Thus KSL a visual- gestural language is a language on its own right since it satisfies all the conditions that have come to be known as properties of human language viz: displacement, discreteness, duality, arbitrariness, cultural transmission and productivity/creativity (Cf Abercrombie (1968); Okombo (1992).

2. REVIEW OF LITERATURE

One valuable article to our study is Roy's (1989) article on “*Features of Discourse in an American Sign Language Lecture.*” In this article, Roy examines the features of discourse that occur in a lecture given in American Sign Language (ASL). Though there are certain distinctions between the two studies in terms of the two languages i.e., one is on KSL and the

other on ASL and despite the fact that Roy's study is on a lecture while the current one is on a sermon, both studies are formal in nature thus Roy's article benefitted our research immensely. For example Roy identified categories of discourse markers in ASL such as: Head nodes, the sign OK and ANYWAY and the lexical sign NOW, NOW THAT etc. Since our study is about how content is structured in discourse through the use of structural devices or linguistic features that mark transition by helping in establishing cohesion, Roy's article was valuable through the identification of discourse markers. Zimmer article in Ceil, L (ed.) (1989) entitled "*Towards a Description of Register Variation in ASL*" describes the use of language sensitive to situational factors which is also the concern of our research. Zimmer videotaped native ASL users in three different situations: A formal lecture in an academic setting, an informal talk and a television interview. The paper though on ASL, helped us gain insight into discourse analysis in SL in general and especially on the formal use of language in a lecture.

A paper in Ochs and Bennett (1977) *Discourse Across Time and Space* by Elinoor entitled "*Why look at unplanned and planned discourse*" gave us an insight into the characteristics of both planned and unplanned discourse. The sermon the subject of our analysis falls under planned discourse.

Theoretically, though the following texts deal with theories of DA based on spoken language, they were valuable references: Schiffrin (1994) *Approaches to Discourse*, Brown and Yule (1983), *Discourse Analysis*- both texts provided background information on the different approaches available in the analysis of discourse. In terms of theoretical issues that specifically deal with sign language, Zimmer (1989) article on "*Towards a Description of Register Variation in American Sign Language*" in Ceil, L (ed.) (1989) was important to our research. This text reviews models of register variation generally and specifically those of ASL. Since our study is about differential use of language specifically in KSL, the models of register variation discussed in Zimmer above assisted us in our analysis of KSL grammatical cohesion.

Halliday and Hasan (1976) examined cohesion and presented a taxonomy of various types of cohesive ties which included:

- Reference – Including antecedents, anaphor relations, the definite article "the" and the demonstrative pronouns.
- Substitution- including such various pronouns and ellipsis
- Conjunctions, involving words like, and, but, yet etc.
- Lexical cohesion- repeated occurrence of the same related lexical items (not the concern of this analysis).

This taxonomy is relevant in the examination of cohesion in KSL formal discourse – a sermon since our focus will be on matters such as reference, substitution, ellipsis, discourse markers and conjunctions.

3. METHODOLOGY

The sermon under analysis was videotaped at All Saints Cathedral in Nairobi. It was given to an all-deaf audience of about 30 people and it was done in Kenya Sign Language

(KSL). Simon Ngigi a deaf preacher delivered the sermon. His preaching organized its message into a sermon - a speech with an organized collection of thoughts. The video tapes containing the sermon were transcribed and analyzed to discover the discourse features used in planned discourse and any situational factors that trigger the use of those discourse features in planned discourse in KSL specifically a sermon.

It is important to note that KSL like most signed languages does not have a written format. The following conventions are used during the glossing; a single slash/stands for a “comma” while a double slash//stands for a “full stop.” Similarly, in the examples of sentences given, the KSL text is written in capital letters to show that the English words used represent signs in KSL and not words in English. The capital letters represent the idea rather than the word.

The following methods of data elicitation were used in this research. The collection of data took a multiple- technique approach. The techniques used include: Introspective evidence, Analytical evidence and Participant observation. The researcher relied on his near native speaker’s competence in inferring important linguistic structures of KSL in the collection of data introspectively. To check on the existence of biases on the part of the researcher, the data was cross checked with native speakers of the language. Deaf research assistant’s video recorded the KSL formal use in the sermon. Participant observation also was used with the researcher playing an established participant role at the scene of study. In this research, the researcher was a non participant observer in the sermon.

4. THEORETICAL FRAMEWORK

This study uses a theoretical framework as its descriptive tool to guide it in terms of what it shall measure or look out for. A theoretical framework is a collection of interrelated concepts just like a theory but in a theoretical framework the concepts are not well worked out nevertheless it makes use of the interrelated concepts in a new way to explain the relationship between those concepts.

Since a theoretical framework interrelates to various theories it allows for an eclectic approach in the analysis of data. The analysis of data in this paper is therefore guided by an eclectic approach.

For instance, in this paper we use the discourse analysis approach used by Halliday and Hasan (1985) who examined cohesion and presented taxonomy of various types of cohesive ties which were used in the analysis of our data.

Similarly, Halliday (1976) also proposed a model that consisted of the field of discourse, the mode of discourse, the tenor of discourse. A fourth category was later added by Gregory and Carroll (1978) – the functional tenor. This model is used in our data analysis to characterize speech situation under analysis for example we were able to analyze the physical setting and social activities that surround and define a speech event in this case a planned speech event – a sermon.

Joss (1968) on the other hand posits five styles ranging from least formal to most formal. These styles include: Intimate, casual, consultative, formal style and frozen. The Consultative style, which we view as an in-between the casual and formal style was essential in our

analysis of formal discourse. Similarly, formal and frozen styles are used in the analysis of planned discourse since they are styles used in formal situations.

Crystal and Davy (1969) discuss factors that help determine language use. They mention three categories of features within their model that in part determine the type of utterances prescribed in particular situations: Province features, status features and modality features. These features assisted us in the analysis of our data since they are basically contextual factors and contextual use of language is the concern of this study.

Ferguson (1959) identified separate spoken language varieties specified for function in a diglossic situation. He identified high (H-) variety - used in formal situations and the low or (L) variety used in colloquial situations. Fischer (2000) also discussed bilingual situations in which one language (SL) plays both roles i.e., H-role and L-role. Different features mark these two. For example, formal or H- role language the concern of this paper, is slower paced, uses large signing space, more clear and more fully executed, uses two- handed variant of signs, non- manual grammatical features (NMG) have to appear with the manual ones. Though based on ASL, these models (Ferguson, Fisher) were useful in the analysis of KSL especially at the level of Formal discourse (H-variety).

5. DISCUSSION: GRAMMATICAL COHESION IN A KSL SERMON

Cohesion generally involves those surface and underlying elements which provide a text with syntactic and semantic unity or what has been referred to as rhetorical glue that binds units together. In this way then cohesion assist readers or listeners see the many parts of a discourse segment and how they are related to one another. Cohesion devices therefore enable us “see the whole animal.” Discourse elements in a text are united by certain links and connections. These links and connections are what are referred to as cohesion devices. They help discourses like sermons to achieve their informational social function. A listener or reader is normally tasked with the charge of interpreting a text. This task is aided by the fact that the writer or speaker guides his reader or listeners through the use of various linguistic devices, which help them, imbue the representation with far more information than that which is overtly present. Cohesion devices make a text cohere through the use of language forms to indicate semantic relations between elements in a discourse. In this analysis of the KSL sermon, we examined cohesion devices in categories of grammatical cohesion.

Grammatical cohesion deals with cohesive devices such as reference, ellipsis, substitution, conjunctions etc. The taxonomy of cohesive devices that are used to achieve grammatical cohesion in the sermon will be examined following Halliday (1985), Halliday and Hasan (1976), Hasan (1971). These devices are exemplified below:

Reference	Proforms
Substitution	
Ellipsis	Ellipsis
Lexical cohesion	Lexical relationships
Conjunction	Connectives

6. GRAMMATICAL COHESION

Cohesion can be viewed as the relations of meaning that exists within a text and that define it as a text. Cohesion can be established in a text either through grammar or through vocabulary. Where it is established through grammar, grammatical cohesion is established, while where it is established through vocabulary, lexical cohesion is achieved. In this section we examine grammatical cohesion the focus of this analysis. Grammatical cohesion relates to the many grammatical devices that can be used to make relations among sentences more definite. Cohesive devices are therefore used to tie pieces of text together in a special way with the aim of helping the reader or listener understand the items referred to, the ones replaced and even the items omitted. Harmer (2004). Furthermore, the combination of sentences using cohesive devices which have semantic relation need a shared linguistic environment for their interpretation. Grammatical cohesion as earlier indicated is concerned with matters such as reference, substitution, ellipsis, discourse markers and conjunctions which will be discussed below.

a) Reference

Brown and Yule (1983) view reference as the relationship which holds between words and things since words refer to things. This view is also held by Strawson (1950) when he claims that referring is not something an expression does; it is something that someone can use an expression to do. From the above therefore, reference denotes recurring expressions that designate the same entity in a text. They correlate lexical recurrence with conceptual recurrence, Beaugrande and Dressler (1981). Reference elements in a text establish a semantic relationship between them in which one of the elements provides the other with meaning.

Halliday and Hasan (1976) establish two types of reference.

1. Situational reference (exophora) deals with elements that refer to the “shared world” outside of the text.
2. Textual reference (endophora) refers to referring elements within the text.

Of the two, endophoric and exophoric reference, endophoric reference is said to be cohesive and will therefore be the focus of our analysis. However, it is important to note that both endophoric and exophoric reference act together to create texture. Texture being the quality of functioning as a unit. For a text to have texture, it must include “ties that bind together” or cohesive ties. However, creation of texture in a text is not the preserve of cohesion alone. Texture is created within text when there are properties of coherence and cohesion, outside of the apparent grammatical structure of the text. Endophoric reference is divided into Anaphoric (this refers to preceding elements) and Cataphoric reference (this refers to following elements).

Endophoric reference in this sermon manifests these ties through:

- Personal references
- Demonstrative references.
- Comparative reference.

All these different types of references help create reference cohesion.

i) Personal Reference

Personal reference includes personal pronouns, possessives, determiners and pronouns. Personal pronouns refer to reference by means of function in the speech situation through the category of person. The category of person describes the number and kind of participants involved in a speech situation. Person is categorized thus:

1st person – the speaker

2nd person – the hearers or readers being addressed

3rd person – other people, animals, or objects being talked about.

In the sermon under analysis, the following identified personal pronouns were used:

YOU, I, WE, HIM, US, ME, HE

In the sermon, the personal reference pronouns can be categorized into those that refer to the speaker or signer and those that refer to the addressee.

1) Those that refer to speaker or signer

These are referring expressions that refer to given entities – that is the first person in KSL. They mark for number thus they appear in both singular and plural. The first person pronouns used are **I** (singular) and **US** (plural) together with their derived forms **ME** and **WE** respectively. They appear in sentences as exemplified below.

1 a) **I KNOW YOU LOOK JESUS BUT**
I know you are looking for Jesus but he
NOW JESUS THERE NO! NO! /ALIVE
is not there anymore. He is alive again.
AGAIN//

b) **HOLIDAY TIME/I WOULD LIKE SEE**
Holiday time I wouldn't want to see
JESUS ON CROSS NO NO/ MAN BLOOD
Jesus on the cross, his blood and
DON'T LIKE INCLUDE NAILING ON
his nailing on the cross.
CROSS//

c) **STAND THERE NEAR DEAD SEE**
They stood near the tomb and saw a group

OTHER JESUS GROUP TOGETHER
 of Jews together with group of teachers
 GROUP TEACHER COME MEET
 going to see the king. They were asked to
 KING/ASK US REMEMBER JESUS
 remember the fact that
 ALIVE THERE JOKE BIG//
 Jesus is alive was a big joke.

d) FEAR NOT/**ME** KNOW YOU LOOK
 Don't fear I know you are looking for Jesus
 JESUS/BUT THERE JESUS NOTHING/
 But Jesus is not here
 JESUS ALIVE AGAIN//
 He is alive again.

e) YOU AFRAID NO/**ME** ASK **YOU**
 Don't be afraid I am asking you to tell
 TELL FOLLOWERS MINE GO GALILEE
 My followers to go to Galilee
 ME THERE//
 I will be there.

In KSL **I**, or **ME** is signed with the index-finger hand form making contact with the signer's chest as illustrated below:

I/ME

Since pronouns are noun equivalents, they function like nouns. Thus the pronouns in (1 a-b) are subjects of the verbs. In 1 (a) the pronoun **I** is subject of the verb **KNOW**. It describes the person who is talking. In 1 (b) **I** also appears utterance initial as the subject of the verb **WOULD**. **ME**, the derived form of **I** also appears in same positions. It appears as the subject of the verb **KNOW** in 1 (d) and the subject of the verb **ASK** in 1 (e). From the above examples, in KSL, what refers to speaker or signer link the speaker cataphorically to other information in the text as exemplified by **I** and **ME** which appear sentence initially in KSL because they are subjects of the sentences.

US in 1 c) the plural of **I** appears sentence medial while it's derived form **WE** appears sentence initial. **WE** or **US** in KSL is signed as illustrated below:

WE/US

It appears that in KSL **US** is the only pronoun that refers to the signer that can appear sentence medial and thus link information anaphorically by referring to the people who were standing near Jesus' tomb (1c above).

2) Those that refer to addressee

Personal reference can also refer to the addressee. These are the second and third person reference pronouns. Those identified in our text include:

	Singular	plural
2 nd person	YOU	YOU
3 rd person	HE/HIM -	

YOU is signed with the index-finger hand form pointing at the reference (see illustration below).

YOU

In KSL, the second person singular and plural is signed **YOU**. **HE** and its derived form **HIM** is the third person personal pronouns used in our text. The use of these pronouns can be exemplified in sentences below:

2 a) I KNOW **YOU** LOOK JESUS BUT
 I know you are looking for Jesus but he is
 NOW JESUS THERE NO NO/ ALIVE
 Not there He is alive again.
 AGAIN/ ANGEL SAY **YOU** LIKE

The angel said if you would
SEE WELCOME//
Like to confirm you are welcome.

b) TODAY GOD ARISE **YOU** DEAD
Today God has resurrected you from the
ALIVE AGAIN// FIRST GOD AROSE
dead you are alive again. First Jesus was
FOR **YOU** FROM DEAD//
resurrected from the dead for you.

c) OTHER PERSON NAME JOSEPH
Another person called Joseph whose sign
SIGN RICH/ COME ASK SOLDIER
name is Rich came and asked the guards to
PLEASE GIVE JESUS BODY TO ME/
give him Jesus' body The guard ordered him
THIS SOLDIER ORDER **YOU** GO ASK
to go and talk to their boss.
OTHER. SOLDIER BOSS//

YOU, a second person pronoun in KSL is a pointing sign just like **I**. It is used deictically to point at the addressee. The context of use will be the determinant as to whether it is being used in the singular or plural form. In 2 (a-b) **YOU** is used as a plural while 2 c) is an example of **YOU** used as a singular pronoun. In 2 (a) **YOU** refers deictically to the people who were looking for Jesus. In 2 (b) **YOU** refers to the congregation deictically. However, in 2(c) **YOU** refers anaphorically to **JOSEPH**.

HE and its derived form **HIM** are the third person personal pronouns identified in the text under analysis. In KSL all the third person personal pronouns are signed deictically by pointing at the side of the signer. When one points on a side, it establishes a reference and thus that pointed side is used to refer to the pronoun consistently. **HE**, **HIM** and **IT** are signed as illustrated below:

HE/SHE/IT

Examples in sentences in the sermon:

3 a) **HE** SOLDIER BOSS ACCEPT

The soldiers' boss accepted and they
FINISH/TOGETHER WENT NAILS
together went and removed the nails and
NAILS OUT/ BODY OUT LAY ON
lay the body on the ground.
GROUND//

b) NOW GOD GIVE LIFE AGAIN MUST

We must believe that God has given us life
BELIEVE GOD CAN/WHY JESUS BODY
again. He can. Why do we have
HAVE THERE/WE BELIEVE
Jesus' body on the cross. We
NO/ MUST TRUST **HIM**//
Don't believe we must trust him

In 3 (a) above, **HE** is used cataphorically to refer anticipatorily to **THE SOLDIERS' BOSS**. Used this way, it has cataphoric reference, in which the referent has been withheld in order to engage the reader's /the listener's attention. **HIM** in 3 (b) on the other hand anaphorically refers to **GOD**. Thus, the third person pronouns can be used to refer both cataphorically and anaphorically. In the anaphoric reference 3 (b) above, **HIM** is used to keep current the identity of the conceptual content that was made plain in advance that is **GOD**. In 3(a) **HE** as a proform is used anticipatorily before the co-referring expression that is, **THE SOLDIERS' BOSS**. In the examples above the pronouns co-refer to elements of the same type. They refer to nouns. Such correspondence has the advantage of making already paired grammatical frameworks re-usable.

Other proforms that indicate personal reference are the reflexive pronouns. In this text only two were identified. Those identified in the sermon include:

2nd person singular – YOURSELF

3rd person singular – HIMSELF

They appear in sentences below.

4 a) GROW YEAR YEAR TWELVE/

He grew to be twelve years.

JESUS **HIMSELF**

Jesus himself was Twelve years.

YEARYEAR TWELVE/AFTER

Afterwards, he held discussions in the

HAVE CHURCH DISCUSS QUESTION

Church and answered

QUESTION QUESTION//

many questions.

b) START WORKWORK/PREACH

He started work and continued preaching in

DIFFERENT DIFFERENT DIFFERENT

Different places. Jesus himself suffered

DIFFERENT DIFFERENT CONTINUE

He experienced suffering.

CONTINUE. CONTINUE/HAVE SUFFER

He himself experienced suffering.

JESUS **HIMSELF**/HAVE EXPERIENCE

Jesus himself experienced a lot of

FINISH THERE/ JESUS **HIMSELF** HAVE

suffering.

c) WE THINK WHAT ABOUT JESUS

What do we think about Jesus being alive

ALIVE AGAIN? YOU MUST BELIEVE

again. You must believe in Jesus

BASI **YOURSELF** JESUS **YOURSELF**/

yourself that's all. Yourself in Jesus

GOD **HIMSELF** RISE JESUS DEAD

You yourself must believe God himself rose

Jesus from the

FINISH//

Dead that's all.

HIMSELF the third person reference pronoun is used to refer to **JESUS** anaphorically in 4 (a and b). **YOURSELF** the second person reference pronoun as used in 4 c) on the other hand used to refer to **YOU**, which in turn refers to the audience. **HIMSELF** is used as an emphatic pronoun thus it appears together with the nominal it emphasizes that is in 4 (a) and (b) **JESUS HIMSELF**. **YOURSELF** also refers retrospectively to **YOU** in the sentence but they are not used together.

The sermon does not make use of the first person singular reflexive pronoun **MYSELF**. This may be due to the fact that the preacher does not need to refer to himself since the sermon is centered around **JESUS** and thus the use of **HIMSELF** mostly referring to **JESUS** and **YOURSELF** mostly referring his congregation.

Possessive pronouns are also used to indicate personal reference. Possessive pronouns appearing in our text include:

HIS – the third person singular masculine possessive pronoun

MY – the first person singular dependent possessive pronoun

Their uses in the sermon can be exemplified as follows:

5 a) ARMY GROUP BEAT JESUS/SAME

Soldiers beat up Jesus. They also

GROUP PIERCE STOMACH **HIS**

pierced his stomach with spears.

USE SPEAR//

b) WE REMEMBER THAT JOKE BIG

We will remember that it is a big joke.

/JESUS AROSE BIG JOKE/**HIS**

That Jesus arose from the dead is a big joke

FOLLOWERS WHISPER COME PICK. His followers came secretly

BODY JESUS/FOLLOWERS THESE

And pieced his body and they

TELL TELL JESUS

whispered telling people

DAYDAY THREE UP AGAIN JOKE

That Jesus arose again on the third day

BIG//

c) YOU AFRAID NO!NO!/ME ASK

Don't be afraid. I am asking you to tell my

YOU TELL **MY** FOLLOWERS GO

followers to go to Galilee

GALILEE ME THERE//

I will be there

The third person masculine possessive pronoun **HIS** is used in 5 (a) anaphorically to refer to **STOMACH** and cataphorically in 5 (b) to refer to **FOLLOWERS**. **MY** in 5 (c) on the other hand refers cataphorically to **FOLLOWERS**. In 5a), the possessive pronoun **HIS** appears after the noun while in 5b) it appears before the noun. It appears therefore that KSL places possessive pronouns either before or after the noun.

Interrogative pronouns were also used in this text. Those used in the sermon can be classified as interrogatives that are used to introduce questions and interrogative adverbs used to form questions. Interrogative adverbs used to introduce questions, represent a piece of missing information that the speaker wants the hearer to supply. This is exemplified by **WHAT** and **HOW**. **WHAT** is also used as an exclamative to add intensity to a question.

There are also interrogative adverbs – used to form questions. In this text **HOW**, **WHY** and **WHO**. Their uses are exemplified below:

6 a) MARY TOGETHER SISTER

Mary together with her sister came to see

COME WOULD LIKE TO SEE JESUS/

Jesus body. They were shocked. What

SHOCK SEE HOLE INSIDE **WHAT**?

did they see in the grave?

FINISH//

b) HAPPEN JESUS CAUGHT/ HAPPEN

It happened that Jesus was caught.

WHAT?

What happened?

c) CARRY BODY JESUS GRAVE

they carried Jesus body to the grave

PEOPLE RETURN STONE GO/ IN

and put the stone Back and went.

THERE **WHAT?** HAPPEN

What happened inside there?

JESUS AROSE

It happened Jesus arose.

d) ISRAEL PEOPLE PATIENT

The Israelites were patient with God.

GOD/WAIT YEAR YEAR FOUR **WHY?**

They waited For four years why?

CHRIST BORN/CHRIST BORN MOTHER

Christ was born. Christ was born to

MARY//

Mary.

e) JESUS GROUP QUESTION QUESTION

The Jews questioned Jesus on different

QUESTION DIFFERENT DIFFERENT

On the cross finally why?

CAUGHT JESUS HANG HIM ON

Because God had decided to

CROSS/JESUS FINAL FINAL **WHY?**

Give Jesus as a sacrifice that's all.

GOD DECIDED GIVE DIED FINISH/

Jesus died along time ago.

JESUS DIED ALSO AGO//

f) BEFORE JESUS DEAD FINISH/

When Jesus had die, the guards were

GUARD INCLUDE THERE/SEE DEAD

Witnesses. They saw he had died but

FINISH BUT PIERCE WITH SPEAR

still pierced him with a spear.

HOW?DEAD FINISH AGO THERE

After he was already dead they

PIERCE PIERCE//.

still pierced his body.

g) IF DEAD ARISE ZERO MEANING

If you die and don't resurrect that means you

GOD BELONG ACCEPT ZERO/

don't belong to God. God will not accept

THROUGH **WHO?** THROUGH **WHO?**

you. Unless you go through Jesus
 JESUS PERSON BASI//
 through Jesus.

WHAT in 6(a) and (b) is used as an exclamative pronoun. In this way it has an intensifying force. **WHAT** used as an exclamative in KSL appears at the end of the statement.

In 6 (a) **WHAT** precedes another intensifier **FINISH**. **WHAT** is thus a pre-intensifier. In this role of an intensifier, **WHAT** refers back to what Mary and her sister, expected and what they saw which was contrary to expectation. In this case, **WHAT** intensifies this fact.

In 6 (b) **WHAT**, intensifies retrospectively the act of Jesus being caught. **HAPPEN WHAT** intensified the unjust nature of his being caught and what happened to him consequently.

In 6 c), **WHAT** plays another role. It functions as an interrogative adverb. As an interrogative adverb, **WHAT** is used to ask a question. In this case a rhetorical question. Rhetorical questions provide connections of what the speaker is saying. These types of questions do not require answers since the speaker supplies the answer immediately after. In Kenyan Sign Language rhetorical questions can be distinguished from real questions in the difference of their use of non-manual grammatical features that include: squinted eyebrows and tilted head (for real questions) and raised eye brows and a light shake or tilt of head (for rhetorical questions).

WHY and **WHO** are also used as interrogatives for rhetorical effect. In 6 (d) and (e), **WHY** appears utterance final followed immediately by the answer to the question asked by the speaker. The same is true with the sign **WHO** in 6 (g). In these instances, the interrogative adverb is used to refer anticipatorily or cataphorically. In 6 (g) **WHO** is used to refer cataphorically to **JESUS**. However, **HOW** in 6 (f) is purely used as an interrogative pronoun – it represents a piece of missing information that the speaker wants the hearer to supply. In this case **HOW** is questioning retrospectively the fact that the guards speared the body of Jesus even after they confirmed he was dead. The speaker does not supply the answer but lets his listeners fill in for themselves.

In the sermon, **WHAT** is used as an exclamative pronoun and as well as an intensifier and also for interrogative purpose used to ask rhetorical questions the same way **WHO**, **WHY** and **HOW** are used in the sermon. As an exclamative pronoun it appears at the end of a statement while as an intensifier it precedes another intensifier.

For any discourse to be understood by a reader or a listener, necessary connectors need to be used so as to achieve cohesive discourse as part of grammatical cohesion. From the above discussion, it is clear that reference cohesion as discussed through the use of personal pronouns, helps to clarify clausal relations. Pronouns bring cohesion in a text by continuing topics already raised since they have to be anchored to some entity in the text which all participants can orient to. The relationship between reference elements is such that a semantic relationship is established between them in which either the antecedent or the precedent provides the other with meaning. Thus reference denotes recurring expressions that designate the same entity in a text. They correlate lexical recurrence with conceptual recurrence. Beaugrande and Dressler (1981). Reference elements in a text establish a semantic relationship between them in which one of the elements provides the other with meaning. As far as the personal pronouns that refer to the speaker are concerned, **I** in KSL can appear utterance initial as the subject of the verb in KSL. **US** the plural of **I** appears sentence medial

while its derived form **WE** appears sentence initial in all instances the pronouns are used to refer to the person who is talking and link him or her to the events in the sentence.

For the Personal reference that are used to refer to the addressee, **YOU** in KSL is used deictically to point at the addressee, but it can also be used to refer anaphorically. These two uses enhance cohesion in the text. Similarly, **HE** and its derived form **HIM** are also signed deictically by pointing at the side of the signer. When one points on a side, it establishes a reference and thus that pointed side is used to refer to the pronoun consistently. **He** and **HIM** can be used both cataphorically and anaphorically. Used as anaphoric reference, these pronouns keep current the identity of the conceptual content that was made plain in advance. They can also be used anticipatorily (cataphorically) before the co-referring expression. These pronouns co-refer to elements of the same type. They refer to nouns. Such correspondence has the advantage of making already paired grammatical frameworks re-usable as pointed out earlier.

Other pro-forms that indicate personal reference that were analyzed above are the reflexive and possessive pronouns. In the sermon, **HIMSELF** and **YOURSELF** were used. **HIMSELF** in KSL formal discourse can be used anaphorically and as an emphatic pronoun. Used as an emphatic pronoun it appears together with the nominal it emphasizes. **YOURSELF** can also refer retrospectively in the sentence to **YOU** but they are not necessarily used together.

Possessive pronouns identified in our sermon are **HIS** and **MY**. **HIS** can refer both cataphorically and anaphorically while **MY** refers cataphorically. It appears that KSL places possessive adjectives either before or after the noun though there is some controversy as to whether KSL places possessive adjectives before nouns. Interrogative pronouns were also used in this text. Interrogative pronouns represent a piece of missing information that the speaker wants the hearer to supply. This is exemplified by **WHAT** and **HOW** from the sermon. Interrogative adverbs – used to form questions such as **HOW**, **WHY** and **WHO** were also identified. **WHAT** in KSL, can act as an intensifier or pre-intensifier in planned discourse. In the role of an intensifier, **WHAT** precedes another intensifier **FINISH** and also refers back or intensifies retrospectively. **WHAT** is also used as an exclamative pronoun. In this way it has an intensifying force. **WHAT** used as an exclamative in KSL appears at the end of the sentence.

ii) Demonstrative Reference

Demonstrative reference is normally achieved through pronouns or determiners, which refers to something in terms of whether it is near or distant from the speaker. Demonstrative reference helps in achieving cohesion in a text through referring by means of location on a scale of proximity. Like all forms of referencing, demonstrative references provide us with referencing cohesion whose main function is to retrieve presupposed information in text and this information must be identifiable for it to be considered cohesive.

Demonstrative reference is made up mainly of pointing signs. “Signers establish reference in particular locations in the signing space and use pointing signs as pronouns to reference to these locations.” Zimmer and Patsake in Valli and Lucas (1995). Pointing signs are used as pronouns and the pronominalization process in KSL involves the indexing of a particular area in the signing space so as to establish referents that can concretely or physically be present or they may not be actually present in the signing space. The signing space can be illustrated as follows: Cf. Wool and Lawson (see figure below).

Demonstrative signs can function both as determiners and as pronouns. They represent two types of contrasts:

- Contrast in number
- Contrast in proximity

The contrast in proximity may be in space or in time. In the sermon, under discussion, the following demonstratives were used:

NEAR FAR
THIS (singular) -
THESE (plural)

Pointing or deictic signs constitute several lexical items (in the sermon only **THIS** and **THESE** were used) and these lexical items may have several functions. Examples:

7 a) **THIS** SOLDIER ORDER GO ASK

The soldier ordered him to go
 SOLDIER BOSS//
 and ask his boss.

b) TODAY JESUS ALIVE/ONE TIME

Jesus is alive today.
 AGAIN BACK WHY?
 One day he will come back why?
THISSON GOD//
 Because he is a Son of God.

c) BUT PERSON **THIS** ALIVE AGAIN//

But Jesus is alive again.

d) FOLLOWERS **THESE** TELL TELL

His followers were saying after three days
 JESUS DAYDAY THREE/
 Jesus arose from the dead.
 UP AGAIN JOKE BIG YES//

This is a big joke

THIS as exemplified in the sentences above is used to refer cataphorically to **SOLDIER** in 7 (a). **THIS** as a demonstrative brings out contrast in proximity in term of nearness in space. The signer will already have indexed a particular area on the signing space and designated it for the **SOLDIER** and then uses pointing signs to refer to **SOLDIER**. **THIS** therefore acts as a pronoun when the signer points at the already located place; he is referring to the **SOLDIER**.

THIS in 7 (b) has anaphoric reference since its antecedent precedes it. **THIS** refers to **JESUS** retrospectively. In 7 (c) **THIS** also has retrospective function since it refers back to **PERSON** in this case **JESUS**.

THESE, is also used in the text as exemplified in 7 (d). **THESE** used here, is also anaphoric since it is co-indexed to **FOLLOWERS** which comes before it.

THIS in 7 (b) and (c) and **THESE** 7 (d) indicate that there is some information that we need to retrieve from somewhere else anaphorically since it makes reference to prior discourse. Its cohesiveness stems from “the continuity of reference whereby the same thing re-enters into a discourse a second time. Halliday and Hasan (1976).

THIS in 7 (a) on the other hand, expresses a cataphoric relationship between the reference itself and its precedent. Thus the linkage between them is to a subsequent thing. In cataphoric relations, the addressee looks forward or the reference item refers to what comes afterwards. In this case **THIS** refers to **SOLDIER**.

The sermon uses singular demonstrative pronouns that refer to objects of people near the speaker in plural or singular these are proximal demonstratives such as: **THIS** and **THESE** which link them to subsequent things or makes reference to prior discourse.

iii) Use of Pronouns (Cross Reference or Substitution) and Ellipsis

Leech and Svartvik (1975) assert that clauses are often connected not only because of a meaning-link but also because they share some content e.g., they may be talking about the same person. In this case there is bound to be repetition. Repeating of shared words and content can be avoided by:

- Cross-reference (using pro-nouns)
- Omitting the repeat elements

These two ways of avoiding repeating words and content outlined above give us two ways of establishing grammatical cohesion in discourse – substitution and ellipsis.

While substitution involves the replacement of one element with another in a text, Ellipsis on the other hand “occurs when the standard of one sentence is incomplete and the missing element(s) can be recovered from a previous sentence unambiguously.” Hoey (1983). McCarthy (1998), views ellipsis as “omission of elements normally required by the grammar which the speaker/writer assumes are obvious from the content and thus need not be raised.” Ellipsis and substitution are however interconnected. Renkema (1993) says, “Ellipsis – the omission of a word or part of a sentence is closely related to substitution. Ellipsis is substitution by zero.” Examples of both Ellipsis and Substitution noted in the sermon include:

8 a) OTHER PERSON NAME JOSEPH
Another person named Joseph his

SIGN RICH/ COME ASK SOLDIER
 sign is rich came and asked the soldiers
 PLEASE GIVE JESUS BODY ME/
 To give him the body of Jesus.
 THIS SOLDIER ORDER YOU GO ASK
 The soldier told him to go and ask
 OTHER SOLDIER BOSS/
 Their boss. When he asked the boss the boss
HE SOLDIER BOSS ACCEPT FINISH//
 accepted.

b) TELL TELL DAYDAY THREE UP
 You must say that it is a big joke that Jesus
 BIG JOKE/FOLLOWER TRYTRY
 arose on the third day.
 STEAL BODY JESUS/FOLLOWER
 His followers tried to steal the body of Jesus
 TELL TELL PEOPLE DAYDAY THREE
 and are telling people that Jesus arose from
 UP DEAD//
 the dead on the third day.

c) ANGLE TELL YOU SHOUT NO! NO!
 The angle said do not shout. I know you are
 NO!/I KNOW YOU LOOK JESUS
 looking for Jesus but
 BUT NOW JESUS THERE NO NO/
 He is not here.
 ALIVE AGAIN
 He is alive again.

d) GIRL HAPPY HAPPY HAPPY/ MIND
 The girls were happy and they were ready to
 READY SEE JESUS/
 see Jesus. Mary and her sister also
 MARY TOGETHER SISTER SAME RUN!
 Ran to go and tell Jesus' followers that
 RUN! RUN! GO TELL FOLLOWERS
 JESUS WAIT THERE//
 Jesus was waiting for them.

e) TODAY JESUS ALIVE AGAIN/BACK
 Today Jesus is alive again.
 WHY? THIS SON OF GOD//
 Why did he come back? Because he is son of God.

f) TODAY GOD ARISE YOU DEAD

Today God has arisen you from the dead.

/ALIVE AGAIN/ARISE

You are alive again he arose from the dead.

DEAD THERE/PERSON CROSS DEAD

He had died on the cross.

FINISH//

Example 8 (a) there is omission of part of the sentence **HE SOLDIER BOSS ACCEPT FINISH**. The part omitted here is that he accepted to give Jesus' body to **JOSEPH**. This information is expressed implicitly not explicitly. Similarly, in 10 (b), there is information which the speaker does not state explicitly but which can be recovered from previous sentences. **FOLLOWER TELL TELL PEOPLE DAYDAY THREE UP DEAD**. Here, the word Jesus is omitted. That Jesus was resurrected after three days. In 8 (c) the word **JESUS** is also omitted in **ALIVE AGAIN**.

In the above examples, the speaker avoids repeating shared words and content through the use of ellipsis or omission. In 8 (a), the ellipsis is of a whole part of a sentence. In 10(b) there is a nominal ellipsis where the noun **JESUS** is left out. In 8 (c) also nominal ellipsis is evident with the nominal **JESUS** being left out. In all these instances, there is sharing of structural components at the surface structure and some of these shared structural components are omitted since the speaker assumes they are obvious from the context. Thus the text processing involving ellipsis is only possible when it involves "a perceptible discontinuity of the surface structure" Beaugrande and Dressler (1981).

Grammatical cohesion through cross-reference (substitution) is exemplified in 8 (d-f). In 8 (d); the lexical item **THERE** is a substitute for Galilee, where Jesus was meant to meet his followers after resurrection. In 8(e), **THIS** substitutes for **JESUS** anaphorically while in 8 (f), **PERSON** is also a substitute for **JESUS**. In 8 (d) and (e) nouns are replaced by a demonstrative adverb and demonstrative pronoun respectively. While in 8 (f) one-noun replaces another **JESUS PERSON**. The proforms used in 8 (d) and (e) **THERE** and **THIS** and the noun **PERSON** is 8 (f) function to carry forward content from previous noun phrases in a text. Texts can be held together by the mechanism of substitution one expression used in the place of another one of the same sense or reference and thus forming a cohesive relationship. Thus the pro- forms do signal the fact that the content is kept alive. The content must first be clearly specified before being re-used later on and thus signal shared knowledge. It is important to note that it is the fundamental relation between the text that forces the reader when he encounters substitution or ellipsis, back into the text to look for a previous expression to substitute, in case of substitution or to provide in case to ellipsis.

As cohesive devices both substitution and ellipsis contribute to compactness and efficiency in discourse. Their usefulness stems from the fact that they make messages shorter to discern and that they make the structure of the sentence tighter.

iv) Comparative Reference

Comparative reference denotes a comparison of two or more things, events, abstractions in terms of some particular in respect of which they are similar or different. Comparative reference signs identified in the text include:

SAME a signaler of similarity and **BUT** a signaler of contrastive information. **Examples:**

9 a) **SAME** JESUS ALIVE AGAIN

Similarly, Jesus is alive again.

FINISH

That's all.

b) GO FAST GO FAST TELL

Go very fast and tell his followers

FOLLOWERS WILL SEE JESUS/GIRL

that they will See Jesus.

HAPPY HAPPY HAPPY MIND READY

Mary and her sister were very happy and

SEE JESUS/MARY TOGETHER SISTER

they prepared themselves psychologically to

SAMERUNRUN GO TELL

see Jesus. They ran to go and

FOLLOWERS JESUS WAITED THERE

tell his followers to wait for Jesus.

c) BIBLE TELL IF PEOPLE DEAD ARISE

The Bible says if the dead were not

ZERO SAME PEOPLE THERE

resurrected, then there would have

ARISE NOTHING

been no resurrection.

d) **SAME** GOD ARISE DEAD

Similarly, if God did not arise,

ZERO/SAME PEOPLE

people from the dead, then

ARISE ZERO

People would not have arisen

SAME in KSL can appear in the sentence initial position, and medial position. In 9 (a) and (d), **SAME** appears in the sentence initial position making it refer cataphorically. In 9 (a), it is co-referenced to **JESUS** which comes after it and in 9 (d) on the other hand, it is co-referenced to **GOD** which also appears after it. **SAME** therefore in the two examples is used to denote that a certain NP is referentially equivalent to a subsequent one. **SAME** is in this case referentially equivalent to **JESUS** and **GOD** in 9 (a) and (d) respectively which appear after it in the sentences above. In this pre- focused part position **SAME** is used for emphatic purposes. It thus puts emphasis on the NP it is co- referenced to.

In 9 (b) and (c) **SAME** appears in a post focus position. In 9 (b), the focused part is **MARY TOGETHER SISTER**. This is the noun phrase that **SAME** is co-referenced to. In 9 (c) **SAME** is co-referenced retrospectively to **PEOPLE DEAD**. In this position **SAME** serves an additive function and its equivalent to 'similarly' or "at that time". In 9 (b) **MARY TOGETHER SISTER** is co-referenced to **SAME** which is equivalent to "at that time" in 9 (c) **SAME** which is co-referenced to **PEOPLE DEAD** is equivalent to 'similarly'.

BUT on the other hand signals comparative reference. It is used to signal contrastive elements in a sentence as the examples below show:

10 a) I KNOW YOU LOOK JESUS **BUT**

I know you are looking for Jesus but

NOW JESUS

Jesus is not here

THERE NO! NO! ALIVE AGAIN//

right now. He is alive again.

b) SAME WAY JESUS CHRIST

Though you can belong to Jesus, there are

BELONG CAN **BUT** IMPORTANT TWO

two important things,

ONE GOD RISE JESUS FROM DEAD/

one God resurrected Jesus from the dead.

SECOND GOD SAVE LIFE FOR YOU

Two God saved your lives

LIVE AGAIN

for you to live again.

c) SOME PEOPLE DEAD DEAD FINISH

Some people died along time but God

BUT GOD

ARISE DEAD//

resurrected them.

In 10 (a) and (b) **BUT** is used to indicate the non-satisfaction of possible or probable or necessary conditions. This is the condition-unsatisfied **BUT** which is semantically equivalent to “yet” and “however.” In 10 (a) the speaker is drawing his hearers attention to the fact that they are looking for Jesus in his grave yet he is alive again. The condition that is unsatisfied expressed by **BUT** is their expectation to find Jesus. In 10 (b) also one can belong to Jesus if they are aware of the two issues enumerated by the speaker. In 10 (c) on the other hand, **BUT** is used as an adversative – to show differences between two events. The antecedent of these events **SOME PEOPLE DEAD DEAD FINISH** expresses sufficient condition for negation of the subsequent. Thus despite their death God resurrected them – **BUT GOD ARISE DEAD**.

BUT can also be used to indicate unexpected events. This function of **BUT** is manifested in 10 (a) and (c). In 10 (a) the people looking for Jesus expected to find him in his tomb **BUT** that was not to be. In 10 (c) also people died **BUT** God has the power to resurrect them.

Comparative reference in the sermon is signaled by **SAME** and **BUT**. **SAME** signals similarity while **BUT** signals contrast. **SAME** also is used to signal an additive function that is equivalent to “similarly” or “at that time.” **BUT** as used serve to signal contrastive reference.

From the foregoing discussion on reference cohesion, following Hammed we can argue that cohesion can be established through personal reference since it keeps track of function

through the speech situation using noun pronouns like “he, him, she, her”, etc. and possessive determiners like “mine, yours, his, hers”, etc. Demonstrative reference on the other hand, keeps track of information through location using proximity references like “this, these, that, those, here, there, then, and the”. Comparative reference keeps track of identity and similarity through indirect references using adjectives like “same, equal, similar, different, else, better, more”, etc. and adverbs like “so, such, similarly, otherwise, so, more”, etc.

v) Discourse Markers and Conjunctions

Grammatical cohesion can also be created and achieved through discourse markers and conjunctions. Discourse markers can be viewed as linguistic elements used by speaker or writer to ease the interpretation of text, mostly signaling a relationship between segments of discourses.

Grammatical cohesion uses grammatical patterns to signal the development of discourse. These patterns also known as discourse markers in some way indicate the speakers’ attitude towards the direction of discourse. Conjunctions which Beaugrande and Dressler (1981) have called Junction “is a device for signaling relationships among events or situations – the use of junctive expressions called conjunctions in traditional grammar.” Conjunctions involve the use of formal markers that relate sentences, clauses and paragraphs to each other. Conjunctions signals the way the writer wants the reader to relate what is about to be said to what has been said before.

Trujillo (2003) came up with a list of discourse markers with the range of possible relationships for Spanish and English which we shall use and adopt (with minor changes) by indicating only those discourse markers identified in text under discussion.

Discourse Markers and Examples in Sermon

I. Appositive	
Dismissive	FINISH, ZERO, NOTHING, NO
II. Additive	TOGETHER, AGAIN, SAME
Adversative	BUT
Listing	FIRST, SECOND etc.
III. Temporal	BEFORE
Comparative	AFTER
Consecutive conditional	IF

Beaugrande and Dressler (1981) identify devices that signal relations among events and situation as junctive devices which include:

Conjunctions	Link things which have same status e.g., and
Disjunction	Link things which have alternative status e.g., or, whether or not
Contra-junction	Link things, which have the same status but appear incongruous or incompatible in the textual world, e.g., but, yet etc.
Subordination	Link things which the status of one depends on that of another, e.g., because etc.

Examples of discourse markers and junctive expressions used in our text are given below:

b) Appositive – Dismissive Discourse Markers

When two words, phrases or clauses in a sentence have the same reference, they are said to be in apposition. **Examples:**

11 a) WHY GOD DECIDE GIVE DEAD

Why did God decide to offer Jesus to

FINISH//JESUS DIE **AGO**//

die along time ago?

b) GOD HIMSELF RISE JESUS DEAD

God himself arose Jesus from the dead.

FINISH//

c) ALIVE AGAIN **FINISH**//

Jesus is alive again.

In 11 (a), **AGO** and **FINISH** are in apposition since they occur together with nouns that refer to the same person or thing. In 11 (a), **FINISH** refers to the fact that **JESUS** had died. **AGO** also refers to the same thing death of Jesus. In 11 (b), **FINISH** is in apposition with the phrase **RISE JESUS DEAD**. In 11 (c), **FINISH** refers to **ALIVE AGAIN** it occurs with **JESUS** which is phonetically null but the context provides for its interpretation. **FINISH** in KSL is signed as illustrated below:

FINISH

According to Akach (1991), **FINISH** is an auxiliary verb in KSL that indicates that an action has been accomplished. Valli and Lucas (1995) also hold the same view when they say that **FINISH** is a completive marker which is used to show that the event being described is completely finished. Apart from the above function identified as performed by **FINISH**, Valli and Lucas also indicate that “**FINISH** has the meaning of “in the past.” It is also used for emphasis. In 11 a), it is used to emphasize the importance of **GOD** offering Jesus as a sacrifice. In 11 (b), it emphasizes God’s power in raising people from the dead. This emphasis of **FINISH** is supplemented by the reference pronoun **HIMSELF**. In 11 (c), the emphasis is

on the fact that **JESUS** is alive again. The appositive **FINISH** as a completive marker is used in the above examples to indicate that the action of the sentences represented by the verbs is completely finished. In 11(a), the “decision,” in (b) “raising” Jesus from the dead and in (c) the fact that Jesus is “alive” – all the action represented by these verbs are completely finished.

The emphatic nature of **FINISH** comes out due to its dismissive force. Thus **FINISH** also functions as a dismissive appositive. That the action is not only finished completely but also the addressee is not allowed any further hearing or consideration of the subject or claim.

Other dismissive apposition markers identified in our text include;

NOTHING, **ZERO**, and **NO**. **NOTHING** and **ZERO** in KSL are signed as illustrated below:

NOTHING

ZERO

Examples:

12 a) SAME GOD ARISE DEAD **ZERO**//
Similarly GOD would not have arisen the dead.

b) BIBLE TELL IF PEOPLE DEAD ARISE
The Bible says that if dead people were not
ZERO/ SAME PEOPLE THERE
arisen, similarly there would be
NOTHING//
no people

c) GOD ARISE JESUS LORD **ZERO**/ALL

If God had not arisen Jesus then all people

PEOPLE ARISE **ZERO**//

would not have been arisen.

d) IF GOD PEOPLE DEAD **ZERO**/ GOD

If people didn't die, God will not have

ALIVE ARISE **NO**/JESUS CHRIST

arisen then Jesus would not

DEAD ARISE **NO**//

have arisen.

e) TELL YOU AFRAID **NO**//

Don't be afraid.

NOTHING and **ZERO** are dismissive markers or negation markers in KSL, when used they do not provide the listener with any chance of further hearing or consideration of the subject. These negation markers normally appear in utterance final position. The three can substitute each other freely without changing the negative meaning of the utterances.

For example 12 (a) above repeated here as

13 a) SAME GOD ARISE DEAD **ZERO**

b) SAME GOD ARISE DEAD **NOTHING**/**NO**

Both sentences would translate as: "similarly God would not have arisen the dead." Using the substitution test, we can also show that while **FINISH** indicates perfective action, **NOTHING**, **ZERO** and **NO** can replace it in utterances to negate the sentences where action was completely finished. Akach (1991)

For example 11 above repeated here as 14:

14 a) ALIVE AGAIN **FINISH**

b) ALIVE AGAIN **ZERO**/**NOTHING**/**NO**

While in 14 (a) **FINISH** represents the perfective nature of the action, in (b) **ZERO**, **NOTHING** and **NO** negates the action to mean "Jesus is not alive again."

c) Additive Discourse Markers

Additive discourse markers identified in the text include: **TOGETHER**, **AGAIN** and **SAME**.

15 a) ANYTIME HAPPEN JESUS

Jesus will come anytime. What is our

COME/WE GOAL DO WHAT/ LIFE

goal. It is important that Jesus

AGAIN IMPORTANT LIFE JESUS

is alive again.

IMPORTANT//

b) GOD KNOW PLAN KNOW PLAN

God has a plan already and Jesus is

READY FINISH/ JESUS LIFE**AGAIN**

Alive again and he is not the same again.

FINISH/ **AGAIN** FACE DAME ZERO//

c) I AM PERSON SOLDIER **AGAIN**

I am acting as a soldier and also as Jesus”

JESUS’ FOLLOWER//

follower.

d) JESUS ALIVE TOGETHER GOD/

Jesus is alive and is with God. The new

PERSON NEW ALIVE **TOGETHER**

Jesus is alive with God.

GOD//

e) SISTER **TOGETHER** BOTH ENTER

Both sisters entered the tomb and saw

SEE BODY NOTHING

nothing.

SAME WAY JESUS CHRIST BELONG

Similarly we can belong to Jesus

CAN/JESUS. BELONG **SAME** TODAY

We can belong to Jesus since

ALIVE **AGAIN** FINISH

he is alive today

AGAIN is used as an additive adjunct in 15 (a – c). In 15 (a) **AGAIN** is used to denote something that has happened once more that is Jesus is alive again (once more). The same is true of the first **AGAIN** in 15 (b). the second **AGAIN** in 15 (b) on the other hand indicates more of “in addition to that,” in addition to the fact that he is alive again, Jesus is not the same. In 15(c) **AGAIN** is used as an equivalent of the English “also” or “both.” **AGAIN** in 15 (a) and the first **AGAIN** in 15 (b) are also used as time-when adverbs to indicate time relations. **AGAIN** used this way i.e., equivalent to “at this very moment.” We can use the substitution test to verify this claim. For example 15 (a) and (b) repeated here as 16 a) and (b) respectively

16 a) ANYTIME HAPPEN JESUS

Jesus will come any time. What is our goal?

COME/WE GOAL DO WHAT/LIFE **AT**

He is alive at this moment his life is

THIS MOMENT IMPORTANT LIFE

important.

JESUS IMPORTANT//

b) GOD KNOW PLAN KNOW PLAN

God already has a plan and at this

READY FINISH/JESUS LIFE AT THIS

moment” Jesus is alive and he is not the

MOMENT FINISH/AGAIN FACE SAME

same

ZERO

When **AGAIN** is used as a modifier in KSL, it is used to mean both “once more” and “at this very moment” e.g., in 15 (a) and in (b) the second **AGAIN**. When used as a pre-modifier e.g., 15(b) (second again), it means “additionally” or in “addition to that”

TOGETHER in 15 (d) and (e), is used to denote “together with.” That is Jesus is alive and he is together with God. Similarly, **TOGETHER** can be used to mean “on the same side of.” This usage is normally in times of conflict or competition Leech and Svartvik (1975). In this case if the competition is between the devil and God, then Jesus is “on the same side of” God. **TOGETHER** is linked to God cataphorically since it refers to God which is used subsequent to it.

SAME 15 (f), on the other hand appears before the focused part. This way it serves an additive function since its use is equivalent to “similarly.” The use of same pre focused part also serves emphatic purposes. **SAME** in KSL is signed as illustrated below:

**SAME****d) Adversative Markers**

Another additive discourse marker which mainly shows adversative relations is **BUT**. Examples:

17 a) SOME PEOPLE DEAD FINISH

Some people were dead but God arose them

BUT GOD ARISE DEAD//

from the dead.

b) ALIVE AGAIN IMPORTANT **BUT**

It is important he is alive again but our goal
ALL GOAL JESUS BASI//
should be Jesus only.

PERSON CROSS DEAD FINISH **BUT**

Jesus on the cross but different Jew groups
JEW GROUP DIFFERENT DIFFERENT
Thought that was the end but Jesus Christ
DIFFERENT THINK THIS DEAD FINSH/
BUT JESUS CHRIST CHEAT DEATH//
cheated death.

BUT is used to signal contrasting information. It is used to bring together clauses by coordinating them. In 17(a) – (c) the first clause is linked to the second using a contrastive coordinator **BUT**. The use of **BUT** in the above examples mainly shows that “the first part of the sentence contains information that is not in concord with the positive evaluation of the second” Hoey. Used this way, **BUT** performs adversative functions to show contrast by comparison of two events in terms of some particular aspect of which they are different.

In 17 (a), the contrast comes out in terms of dead and alive – people died **BUT** God resurrected them. In 17 (b) the fact that Jesus is alive again is important however most important is to have Jesus as one’s goal. 17 (c) the contrast comes out where despite Jesus being dead the Jews thought it was the end but Jesus cheated death.

BUT is also used to indicate events which are unexpected. The fact that God arose the dead in 17 (a) for example is unexpected as indicated by the use of **BUT**. This usage is also exemplified in 17 (c) where Jesus’ ability to cheat death was highly unexpected.

e) Consecutive Conditionals

Another way in which grammar provides for putting clauses together apart from coordination is subordination. In this text the subordinate conjunction **IF** is used as exemplified below:

18 a) **IF** GOD PEOPLE DEAD

If people didn’t die, God would not have
ZERO/GOD ALIVE ARISE
arisen them. Jesus Christ would
NO/JESUS CHRIST DEAD ARISE NO//
not have been arisen.

b) BIBLE TELL **IF** PEOPLE DEAD

The Bible tells that if dead people didn’t
ARISE ZERO SAME PEOPLE THERE
arise, there
ARISE NOTHING//

c) **IF PEOPLE BELIEVE DEAD ARISE**

If people believe that the dead can be
ALIVE PERSON WILL LIVE AGAIN
 resurrected And he alive again then
CAN/ ALIVE PERSON WILL AGAIN
 they can live again
CAN/ALIVE AGAIN CAN//
 They can live again.

IF DEAD ARISE ZERO MEANING GOD

If the dead are not resurrected that means
BELONG ACCEPT ZERO//
 they don't belong to God.

Conditional clauses introduced by **IF** are related to reason clauses. Conditionals as lexical signalers express relations between facts. They indicate the consequences of something and they also articulate a condition upon which the topic being discussed depends. In other words, conditionals express a dependency relationship between facts or propositions.

In 18 (a) the dependency relationship comes out in the fact that dead people being arisen is conditional on their being dead in the first place. If they didn't die then they wouldn't have been arisen. Similarly Jesus wouldn't have been arisen if he hadn't died. In 18 (b), if the people in the Bible didn't die and arise, then people today would not be arisen too. In 18(c), if people believe that the dead can be arisen and be alive again they too can live. In 18 (d) if the dead did not arise, it meant God did not accept them.

IF as used in the above examples relates facts in the proposition by stating the contingent dependence of one circumstance to another. **IF** sometimes expresses an open condition. This is a condition where the truth of falsehood of what is described by the sentence is open or unknown. Similarly, **IF** can be used to expresses hypothetical conditions or an unreal condition. In 18 above, **IF** seems to be used solely to express open conditions since the truth or falsity of the idea expressed in these sentences are open or unknown.

f) Listing Additive Markers

Other additive discourse markers are those used to list what is being said. These additives consist of signs that indicate additions or continuation as exemplified below:

19. **GOD POWERFUL/LORD JESUS**

God is powerful. He arose Jesus from the
AROSE DEAD/FIRST GOD AROSE FOR
 dead. First God arose from the dead for us.
YOU FROM DEAD/SECOND GOD
 Second God also arose us from
AROSE US BURRY DEAD/ GOD
 the dead. He is powerful.
POWERFUL FINISH//

Listing signs exemplified above – **FIRST** and **SECOND** are chronological linkers. They indicate addition or continuation of ideas. They connect ideas in a series or a list. According to Crombie (1985) “the relation of chronological sequence provides the semantic link between event propositions one which follows the other in time.” In the above examples, **SECOND** follows **FIRST** in a chronological order. The signs **FIRST** and **SECOND** are made on the fingers; the fingers serve what Liddel (1996) calls articulatory function. He refers to the point on the body or in the signing space that serves this function (articulatory function) as the locus. The fingers, used as the locus to show the listing, serve the referentially equality function.

FIRST and **SECOND** above are examples or anticipatory signaling since listing comes before its lexical realization or what the signaling is referring to. In this case **FIRST** is referring to the fact that God rose from the dead for us. **SECOND** on the other hand refers to the fact that God also arose us from the dead.

g) Temporal Markers

Other signs that are used to specify time of the event being described in our text include: **NOW, TODAY, AGO AGO, AFTER, BEFORE.**

20 a) OTHER GROUP SOLDIER

The guards guarding the tomb fainted and
BEFORE FALL **NOW** UP AGAIN//
then they woke up again.

b) **NOW** GOD GIVE LIFE AGAIN MUST

Today God has given us life again. We
BELIEVE GOD CAN//
must believe God can do this.

c) **TODAY** GOD ARISE YOU DEAD

Today God has arisen from the dead and is
ALIVE AGAIN//
alive again.

d) **TODAY** THINK JESUS FINISH **AGO**

Today you may think Jesus died along time
AGO/JESUS BODY ALIVE AGAIN//
ago but he is alive again

e) **BEFORE** JESUS EXPERIENCE HAVE

Sometimes back Jesus had experienced
SUFFER SUFFER SUFFER WORK
suffering while doing his work.
WORK TIRED THERE//

f) **BEFORE** STORY MATTHEW

The story of Matthew gave us a different
DIFFERENT DIFFERENT WORD GIVE//
picture.

g) **GROW** YEAR YEAR TWELVE/ JESUS

He grew to be twelve. Jesus was twelve
HIMSELF YEAR YEAR TWELVE/
years old when he held discussion in
AFTER HAVE CHURCH DISCUSS/
churches and answered
QUESTION QUESTION QUESTION
different questions.
QUESTION HAVE//

h) **AGO** AGOSEE DEAD FINISH/ JESUS

You may think Jesus died along time
ALIVE AGAIN FINISH//
ago but he is still alive.

i) **WHY** GOD DECIDED GIVE DIED

Why did God sacrifice his own son/ Jesus
FINISH/ JESUS DIED **AGO**//
died for us along time ago.
NOW in KSL can serve two functions:

- As a marker of present time. In this use, it can be substituted with time reference “today” or at “this time” **NOW** in this instance is mainly used as a temporal marker.
- As a discourse marker indicating a “shift into a new topic or sub topic as well as calling attention to what is coming next in the text” Roy (1981). **NOW** thus introduces a new stage in the sequence of thought. Quirk and Greenbaum (2004).

When **NOW** for example is used as a marker of present time. It identifies a point or period of time directly. It thus acts as a “time-when” conjunction. **NOW** in 20 (a) is an example of the second use. It is used as discourse marker. It is used to introduce a new stage in sequence of thought or to begin a discussion. The discourse marker **NOW** can be distinguished from **NOW** the marker of present time by virtue of the fact that it mainly occurs sentence initial as is the case, in 20 (a). **NOW** is calling attention to what is coming next in the text. The fact that we must believe that God gives life again.

It should be noted also that in KSL the sentence initial **NOW** can also act as marker of present time apart from being a discourse marker. Thus when **NOW** appears sentence initial in KSL; it serves dual functions – as a discourse marker and the marker of present time.

Another “time when” adverb used in our text is **TODAY**. In Example 20c) and (d), **TODAY** is used to identify a point or period of time directly. In 20 c) and (d) **TODAY** means “at this point in time.” In 20c), it means that “at this point in time,” God has saved you from

sins and you are alive again. In 20(d), **TODAY** means “at this point in time,” you may think Jesus died a long time ago. However, he is alive again.

BEFORE as a discourse marker that indicates time relations is exemplified in 20 (e) and (f). **BEFORE** is used as a “time when” adverb that identifies time indirectly by reference to another point in time understood in the context. **BEFORE**, refers to past time but not too distant past. It refers to a very “short time ago” as compared to **AGO AGO OR AGO** in 29(h) and (i). These two signs **AGO AGO** and **AGO** – indicate a distant past – “a long time ago” together with **BEFORE** they are used for backward directionality.

AFTER, 20 (g), on the other hand, is a marker of future tense. It is used to express forward directionality in which the earlier event “when Jesus turned twelve years old” provides reason for the later event “his going to hold discussion and answering questions in church.”

Time in KSL can be indicated by the imaginary time line that has traditionally been seen to run perpendicular to the signer’s body. The area near the signer’s torso has a general meaning of “present” the area farther away has a meaning of “future,” the areas over the shoulder has a general meaning of “past” Valli and Lucas (1995).

From the above discussion, as Halliday and Hasan (1976) put it Conjunction acts as a semantic cohesive tie within text in four categories: additive, adversative, causal and temporal. Additive conjunctions act to structurally coordinate or link by adding to the presupposed item and are signaled through “and, also, too, furthermore, additionally,” etc. Additive conjunction may also act to negate the presupposed item and is signaled by “nor, and...not, either, neither”, etc. In the sermon under analysis the following KSL examples were identified: **TOGETHER**, **AGAIN AND SAME**. Adversative conjunctions act to indicate “contrary to expectation” (ibid: 250) and are signaled by “yet, though, only, but, in fact, rather,” etc.... temporal and links by signaling sequence or time. Some sample temporal conjunctive signals are “then, next, after that, next day, until then, at the same time, at this point,” etc. In the sermon under analysis the following KSL example was identified: **BUT**

CONCLUSION

From the above discussion, we have observed that texture in the sermon is achieved through grammatical cohesion which is achieved through grammar. The structuring of content in discourse through the use of structural devices or linguistic features that mark transition help in establishing cohesion. Discourse elements in a text are united by certain links and connections. These links and connections are what are referred to as cohesion devices. Grammatical cohesion the concern of this paper is concerned with matters such as reference, substitution, ellipsis, discourse markers and conjunctions.

Reference is concerned, with the relationship which holds between words and things since words refer to things. Brown and Yule (1983). Thus reference elements in a text establish a semantic relationship between them in which one of the elements provides the other with meaning. It is clear that reference cohesion by use of personal pronouns, helps to clarify clausal relations. Personal pronouns therefore link elements in a text by continuing topics already raised since they have to be anchored to some entity in the text which all participants can orient to. In this way it helps in bringing cohesion. The relationship between

reference elements is such that a semantic relationship is established between them in which either the antecedent or the precedent provides the other with meaning. In KSL, personal reference pronouns especially those that refer to the addressee can be used deictically to point at the addressee, and can also be used to refer anaphorically for example **HE** and **HIM**. When they are used for anaphoric reference, these pronouns keep current the identity of the conceptual content that was made plain in advance. When used anticipatorily (cataphorically), they appear before the co-referring expression and they co-refer to elements of the same type. In both uses above they enhancing cohesion in discourse. The reflexive pronouns **HIMSELF** and **YOURSELF** can be used anaphorically and also as emphatic pronoun. When use anaphorically they refer back to a nominal that had been mentioned earlier and they are thus linked to the same. On the other hand, the cohesiveness of interrogative pronouns such as **WHAT** and **HOW** stems from the fact that they represent a piece of missing information that the speaker wants the hearer to supply. Demonstrative reference helps in achieving cohesion in a text through referring by means of location on a scale of proximity. **THIS** and **THESE** for example indicate that there is some information that we need to retrieve from somewhere else anaphorically since it makes reference to prior discourse.

Use of pronouns (cross reference or substitution) and ellipsis (Omitting repeated elements) are two ways of avoiding repeating words and content and they are used to establish grammatical coherence in discourse. As cohesive devices both substitution and ellipsis contribute to compactness and efficiency in discourse since they make messages shorter to discern and that they make the structure of the sentence tighter. Cohesion can also be achieved through use of comparative reference which denotes a comparison of two or more things, events, abstractions in terms of some particular in respect of which they are similar or different. Examples in the sermon include: **BUT** and **SAME**. While **SAME** signals similarity, **BUT** signals contrast.

Grammatical cohesion can also be created and achieved through linguistic elements used by speaker/writer to ease the interpretation of text, frequently signaling a relationship between segments of discourse or discourse markers in the sermon, the following were identified: Appositive – dismissive discourse markers e.g., **FINISH**. Other dismissive apposition markers identified in our text include; **NOTHING**, **ZERO**, and **NO. NOTHING** and **ZERO**.

KSL makes use of additive discourse markers like **TOGETHER**, **AGAIN** and **SAME** to achieve cohesion. Similarly, **BUT** an additive discourse marker which mainly shows adversative relations is also used for the same. KSL also makes use of additive discourse markers that list what is being said e.g., **FIRST** and **SECOND**. Subordination is one of the ways used for putting clauses together. In the sermon the subordinate conjunction **IF** is used for this cohesive function.

Finally temporal markers used to specify time of the event being described in our text include: **NOW**, **TODAY**, **AGO** **AGO**, **AFTER**, **BEFORE**. These temporal adverbs are used to link event in discourse in terms of time.

ABSTRACT

A novel computer-based adaptive test of ASL ability known as the American Sign Language Discrimination Test (ASL-DT) recently has been developed at the Rochester Institute of Technology's National Technical Institute for the Deaf (RIT/NTID). The ASL-DT is a measure of learners' sign recognition ability. Specifically, the test measures the ability to discriminate phonological and morphophonological contrasts (minimal pairs) in ASL. Both the item content and test administration methodology differ substantially from procedures currently used for the assessment of second language (L2) learners' sign language abilities. Using a paired comparison discrimination task and Rasch analysis to model item difficulty and person ability, the ASL-DT provides an objective, valid and reliable measure of ASL skills that can serve as a proxy measure of ASL proficiency (Bochner et al., 2016).

In this chapter, we report the results of a study designed to enlarge the ASL-DT item pool to expand the effectiveness of the test across the full range of L2 learners' ASL abilities. A set of 280 items was administered to a sample of 178 adults having ASL proficiency levels extending from beginners to native signers. Forty-eight of the items

were used in previous research (Bochner, Christie, Hauser & Searls, 2011; Bochner et al., 2016), and 232 items were newly developed.

Goals of the study included providing additional evidence of the test's reliability and validity, as well as providing preliminary evidence of the effectiveness of the adaptive test. The chapter builds upon previous work indicating that evaluation of learners' ability to recognize linguistic contrasts can provide useful information about their acquisition of ASL (Bochner, Christie, Hauser & Searls, 2011) as well as previous work indicating that the ASL-DT may provide a useful complement to measures such as the Sign Language Proficiency Interview (SLPI) and the American Sign Language Proficiency Interview (ASLPI) in comprehensive sign language assessment programs (Bochner et al., 2016).

INTRODUCTION

Sign languages are important vehicles of communication and culture within Deaf communities, as well as in educational and other programs serving Deaf people. Many different sign languages are used in Deaf communities throughout the world, each having its own phonology, morphology, syntax and lexicon. Gallaudet University (Gallaudet Library, nd) lists 271 different sign languages used around the world in Europe (e.g., British Sign Language, German Sign Language), Africa (e.g., Ethiopian Sign Language, Zimbabwean Sign Language), the Americas (e.g., American Sign Language, Nicaraguan Sign Language, Brazilian Sign Language), Asia (e.g., Indian Sign Language, Chinese Sign Language), the Middle East (e.g., Israeli Sign Language, Saudi Arabian Sign Language), and Oceania (e.g., Australian Sign Language, Samoan Sign Language).

This chapter describes a novel approach to the assessment of second language (L2) learners' abilities in American Sign Language (ASL). Although ASL is one of the most commonly taught second languages in American colleges and universities (Goldberg, Looney & Lusin, 2015), few assessment instruments have been developed for the evaluation of ASL ability in L2 learners. The dearth of sign language tests for L2 learners, especially tests of sign language reception, poses a problem for instructional programs because of the need for documenting instructional outcomes and program effectiveness, appropriate course placement, and learners' proficiency. Similarly, the dearth of such tests may pose a problem for teacher certification programs because of the need to obtain valid and reliable measures of candidates' ASL proficiency. The scarcity of valid and reliable tests is not unique to ASL. Inspection of the Sign Language Assessment website (www.signlang-assessment.info/) provides an indication of just how scarce sign language tests are, especially tests intended for adult L2 learners.

Tests of ASL Ability: The Sign Language Proficiency Interview (SLPI: Caccamise & Newell, 1995; Newell, Caccamise, Boardman & Holcomb; 1983) probably has been the most widely used and well-known measure of adult L2 learners' ASL ability over the past 20-25 years. It was developed at the National Technical Institute for the Deaf (NTID) in the 1980's. The SLPI is primarily an expressive measure in which the test taker engages in conversation with a trained interviewer and produces a sample of signed discourse that is recorded on video and subsequently evaluated by a panel of three trained raters. The SLPI was modeled on the American Council on the Teaching of Foreign Languages' Oral Proficiency Interview (OPI) and, like the OPI, the reliability and validity of the SLPI are problematical in several respects (Chalhoub-Deville & Fulcher, 2003). Specifically, the interview procedure and the

assignment of ratings are inherently subjective and susceptible to situational and rater bias. Nevertheless, one published study has reported evidence of interrater reliability and very limited and indirect evidence of construct validity (Caccamise & Samar, 2009). Additional evidence of reliability and validity is sorely needed, however. In the absence of affirmative psychometric evidence, the test's validity and reliability must be considered problematical.

The methodology used in the SLPI has been applied in a similar test known as the American Sign Language Proficiency Interview (ASLPI: www.ets.org/praxis/ct/aslpi/ and www.gallaudet.edu/asl-diagnostic-and-evaluation-services/). The ASLPI closely resembles the SLPI (and by extension, the OPI). Both tests engage the respondent in a 20-25 minute conversation that is intended to provide a holistic measure of ASL proficiency using an 11-point ordinal rating scale. The conversation is recorded on video and evaluated by a panel of three trained raters. The rating procedure used in both tests explicitly considers the dimensions of grammar, vocabulary, production accuracy, fluency, and comprehension. The tests' administration and scoring procedures are very similar to one another, as are their rating scales.

The ASLPI is distributed by the Praxis testing program at the Educational Testing Service (ETS). It is intended to measure the overall ASL proficiency of candidates planning to teach ASL or Deaf and hard-of hearing students in primary and secondary schools. The test also has been used to evaluate the ASL ability of faculty and staff at Gallaudet University and other institutions. The test is delivered and evaluated by ASL Diagnostic and Evaluation Services at Gallaudet University, which has reported good evidence of its reliability and limited evidence of construct validity (www.gallaudet.edu/asl-diagnostic-and-evaluation-services/). The evidence of construct validity indicates that the ASLPI measures a unified construct, and ASL Diagnostic and Evaluation Services interprets this construct as overall ASL proficiency. As with the SLPI, additional data are needed to substantiate the test's validity.

A third test of ASL ability designed for prospective teachers is the American Sign Language component of the California Subject Examinations for Teachers (CSET: ASL). Developed by the California Commission on Teacher Credentialing (CST) and Pearson Education, Inc. (CST, 2013; Professional Services Committee, 2009), the CSET: ASL is composed of three separate subtests each of which contains a combination of multiple-choice and constructed-response questions. The first subtest covers literary and cultural texts/traditions and cultural analysis and comparisons. The second subtest covers general linguistics, language structures, contrastive analysis, sociolinguistics and pragmatics. The third subtest covers error analysis, comprehension and production.

A fourth test of ASL ability designed for prospective teachers is the GACE American Sign Language Assessment developed for the Georgia Professional Standards Commission and distributed by the Praxis program at ETS (http://gace.ets.org/s/pdf/gace_taa_g_american_sign_language.pdf). The first part of the GACE test consists of multiple-choice questions covering a range of content area knowledge from fields associated with language teaching and learning, as well as the ability to apply principles from these fields. The second part of the test consists of a 20-minute interview conducted in ASL covering five questions.

Unlike other measures designed for adult L2 learners, the American Sign Language Discrimination Test (ASL-DT) is a computer-based adaptive test of sign recognition ability. The test measures L2 learners' ability to discriminate phonological and morphophonological contrasts (minimal pairs) in ASL. Using a paired comparison discrimination task and Rasch

analysis to model item difficulty and person ability, the ASL-DT provides an objective, valid and reliable measure of ASL skills that can serve as a proxy measure of ASL proficiency. Both its item content and test administration methodology differ substantially from procedures currently used in other tests of ASL abilities (Bochner et al., 2016).

The ASL-DT is an objective assessment that can help to overcome some of the subjective factors that can compromise the validity of subjective proficiency tests as the SLPI and ASLPI for certain individuals under some testing conditions. Expressive tasks, such as the SLPI and ASLPI, provide opportunities for the test taker to control their responses and avoid problematic or difficult constructions, at least to some extent. This feature of expressive tasks introduces another potential source of measurement error in test scores. In contrast, receptive tasks, such as the ASL-DT, require test takers to respond to items without permitting them to avoid challenging constructions.

ASL Proficiency: Spoken languages having a written form are comprised of four correlated components of language proficiency (speaking, listening, reading and writing), as has been demonstrated in studies involving the paper-based Test of English as a Foreign Language (TOEFL: Educational Testing Service, 1992) and generally assumed within the field of language testing (ACTFL, 2012). In a recent study of the factor structure of the internet-based TOEFL, a single higher-order general factor (L2 ability) and four first-order factors corresponding to the four components of language proficiency were identified. The loadings for the four first-order factors on the higher-order general factor were as follows: Listening = 0.97; Reading = 0.91; Writing = 0.91; and Speaking = 0.78 (Sawaki, Stricker & Oranje, 2009). These results confirm that the receptive and expressive dimensions of language processing are closely correlated components of overall language proficiency, suggesting that receptive measures capture a general dimension of language proficiency.

In languages that do not have a written form, such as ASL and other natural sign languages, language proficiency is composed only of a visual receptive and a manual expressive component. Assuming that the associations between phonological discrimination and language comprehension and between the receptive and expressive dimensions of language found in previous studies of other languages extend to ASL, the ability to discern phonological and morphophonological contrasts in ASL should provide a proxy measure of overall ASL proficiency. For example, in a study of an older version of TOEFL, Pike (1979) found that subjective evaluations of expressive language (i.e., oral interviews and writing samples) correlated closely with objective scores on test sections evaluating receptive dimensions of language use and language knowledge (i.e., listening comprehension, reading comprehension, vocabulary, and grammar). Pike's findings are indicative of the relationships among the sub-skills comprising language proficiency and lend support to the statement that "it is commonly recognized that these skills are interrelated; persons who are highly proficient in one area tend to be proficient in the other areas as well" (Educational Testing Service, 1992, p. 32).

Purpose: This chapter builds upon previous work indicating that the evaluation of learners' ability to recognize linguistic contrasts can provide useful information about their acquisition of ASL (Bochner, Christie, Hauser & Searls, 2011), as well as previous work indicating that the ASL-DT may provide a useful complement to measures such as the SLPI and ASLPI in comprehensive sign language assessment programs (Bochner et al., 2016). Specifically, the chapter reports the results of a study designed to enlarge the ASL-DT item pool to expand the effectiveness of the test across the full range of L2 learners' ASL abilities.

A set of 280 items was developed and administered to a sample of 178 adults having ASL proficiency levels extending from beginners to native signers. Secondary goals of the study included providing additional evidence of the test's reliability and validity, as well as providing preliminary evidence of the effectiveness of the adaptive test. The ASL-DT adaptive test is available at <https://apps.ntid.rit.edu/ASLRC/login/login.php>.

METHOD

Participants: The participant sample was composed of 178 individuals ranging in age from 12 to 58 years (mean = 22.2 years, sd = 6.1). Participants were asked to provide a self-evaluation of their ASL skills on a scale of 1= no ability and low ability, 2= intermediate ability, and 3= high and native-like ability, as well as other demographic information as displayed in Table 1.

Test Materials: A set of 280 items was developed and recorded on digital video for presentation to participants. Forty-eight of these items were newly recorded versions of the items used in previous research (Bochner et al., 2011; Bochner et al., 2016), and the remaining 232 items were newly developed and recorded. The items were developed by a team of fluent Deaf signers who teach ASL and Deaf Studies at NTID, and some of them were modified based on feedback from the native signers who produced the signed utterances on video. The items consisted of pairs of ASL utterances, most of which contained linguistic contrasts. The test items were divided into a set of five linguistic categories. Four categories contained phonological contrasts: Location (47 items), Orientation (30 items), Handshape (58 items), and Movement (53 items). One category contained morphophonological contrasts in number incorporation, directional verbs, noun classifier usage, and verb inflection: Complex Morphology (40 items). The sixth and final category did not contain any contrasting linguistic elements: Same (52 items). Examples of each category are provided below:

Orientation:	WE <i>SUSPENDED</i> /GOOD-FRIEND HARD BELIEVE "It is hard to believe that we're suspended!" "It is hard to believe that we're good friends!"
Handshape:	<i>POTATOES</i> /TIMING GOOD "The potatoes are good." "The timing is good."
Location	WOW YOU <i>SMART</i> /LUCKY "Wow, you are smart." "Wow, you are lucky."
Movement	<i>MAN-IX (POINTING)</i> HIKING/MAN-IX AWKWARD "That man is hiking." or "The man is hiking." "That man is awkward." or "The man is awkward."
Complex Morphology	NORMAL AGE LEARN+++

LANGUAGE WHEN (rhq) AROUND TWO-YEARS-OLD/THREE-YEARS-OLD	
“The normal age to acquire language is approximately 2 years old.”	
“The normal age to acquire language is approximately three years old.”	
MY DOG-HAIR THICK (CL:C)/THIN (CL:G)	
“My dog’s hair is thick.”	
“My dog’s hair is thin.”	
Same	STORY-IX (POINTING) UNDERSTAND?
	Do you understand the story?

* $p < .05$; *** $p < .001$

Procedure: Each test item contains two pairs of ASL sentences. The sentences range in length from three to about 10 signs, with most sentences containing 5 – 7 signs. Each pair of sentences includes a standard sentence followed by a comparison sentence. The sentences are identical except for one contrasting element in items containing phonological and morphophonological contrasts. The contrasting element represents a minimal pair. The test taker must decide if the sentences in each pair are the same or different from each other and respond by selecting ‘Same’ or ‘Different’ with a computer mouse. In effect, each sentence pair represents one trial and, for each item, the test taker must respond to two trials. Any combination of ‘same’ and ‘different’ (S and D) trials is possible, allowing for four potential response outcomes: S-D, D-S, D-D, and S-S. Although two responses are required for each item, an item is scored correct if and only if responses to both trials are correct. No partial credit is awarded. The reason each item consists of two trials with all combinations of

response outcomes being possible is that two trials increase the difficulty of the task and reduce chance-level performance.

The assessment procedure is illustrated below in the representation of one item (two trials). In this example, an English gloss of the ASL sentence is presented with the contrasting element (minimal pair) underlined. The same standard sentence is used in each pair.

Trial 1

BUS, IX-GROUP-CHILDREN WAIT (standard sentence)

“The group of children is waiting for the bus.”

BUS IX-GROUP CHILDREN WAIT+++ (comparison sentence)

“The group of children is waiting a long time for the bus.”

Trial 2

BUS, IX-GROUP-CHILDREN WAIT (standard sentence)

“The group of children is waiting for the bus.”

BUS IX-GROUP CHILDREN WAIT (comparison sentence)

“The group of children is waiting for the bus.”

Video Recordings: Test stimuli were produced by three native signers, two males from Michigan and one female from Louisiana. In most cases, the standard and two comparison sentences comprising each item were produced by different signers. The purpose of varying signers within each item was to enhance non-contrastive (allophonic) variation in sign production associated with individual and dialectal differences among the signers. As such, our intent was to create a set of natural, yet variable stimuli. The objective here was to make the discrimination task more challenging and, at the same time, more authentic for respondents. In actual communication situations occurring in the real world, variation of this sort is ubiquitous and frequently encountered by L2 learners in their interactions with native signers.

All utterances were produced in a TV studio with proper lighting and background, and digitally recorded by a professional videographer. The signers watched a recording of each utterance as a prompt, and then attempted to replicate it three times under the supervision of a fluent signer who directed each recording session. The videographer worked with a native signer to select the best (clearest and most representative) utterances and edit the selected utterances into a set of mp4 files. The mp4 files comprising each item were reviewed on three separate occasions by a team of fluent signers to insure their accuracy and consistency. As a result, the utterances contained in the test have been carefully and thoroughly checked to assure quality and accuracy.

Data collection: The 280 items were divided into eight separate lists of equal length. A maximum of five lists were self-administered by each participant over a period of a few weeks typically 2-4 weeks. Before data collection began, each participant completed a demographic questionnaire that enabled us to collect information regarding their age, gender, experience with ASL, self-evaluation of ASL proficiency and other demographic characteristics. Each participant also completed a set of 5-10 practice items prior to engaging in data collection. To ensure that they understood the task, practice was terminated after the participant responded correctly to at least three consecutive items.

In addition to completing a maximum of five lists of items, a small set of participants also completed one adaptive testing session. The adaptive testing software was modeled on an

adaptive test of speech recognition developed by two of the authors (Bochner, Garrison & Doherty, 2015). The test materials were drawn from the pool of 280 items administered to participants in this study, which had undergone a preliminary Rasch scaling analysis to determine their difficulty values as described below.

Adaptive testing and the Rasch model: The Rasch model of person measurement (Wright & Stone, 1979) has been developed within a mathematical framework known as item response theory (IRT). The model can be applied to the analysis of data and used in the scaling and selection of items in adaptive testing. The Rasch model is the simplest IRT model and contains only one parameter; i.e., item difficulty. Item difficulty is an intrinsic parameter of IRT models, with variations in item difficulty being necessary for the creation of item pools used in adaptive testing. Like the stimuli used in adaptive psychophysical procedures such as vision testing, the stimuli used in adaptive testing are scaled along a continuum extending from low to high degrees of magnitude. However, rather than representing a physical construct such as the size of letters on an eye chart, the continuum in this instance represents a domain of human performance, sign recognition ability (Bochner et al., 2011; Bochner et al., 2016).

The Rasch model was used to quantify the difficulty of test items scaled along the continuum of sign recognition ability. The continuum provides an implicit hierarchy that enables the adaptive testing procedure to utilize an “up-down” method of item selection to array respondents on the same scale as the items. When data are found to fit the model, the measurement of persons and calibration of items enable us to place persons and items on a common scale that functions according to the rules of arithmetic (Shaw, 1991). This scale uses a logarithmic unit of measurement known as the logit to express both item difficulty and person ability.

Adaptive testing offers an efficient and precise approach to the measurement of human abilities. The approach is efficient because it requires a minimum number of items, and it is precise because standard errors are specific to individual respondents and are estimable (and controllable) during the testing process. The standard error associated with the respondent’s performance is used to limit the range of difficulty from which items are selected for presentation within each test session. In limiting the range of difficulty from which items are selected, the up-down procedure minimizes measurement error.

An adaptive test like the ASL-DT requires a large pool of items distributed over a wide range of difficulty. The up-down procedure requires an item pool having a great deal of redundancy in difficulty values because the procedure must have a sufficient number of items available within low, intermediate and high levels of difficulty, as well as points in between. Using the standard error as described above, the up-down procedure administers items within an increasingly narrow band of item difficulty to precisely bracket the respondent’s level of sign recognition ability. Since testing terminates when items within the range delimited by the standard error have been exhausted, it is important for the item pool to contain a significant amount of redundancy in difficulty values so that reliable results can be obtained. It also is important to have sufficient diversity in the item pool so that in subsequent test sessions, respondents are not presented with too many items repeated from prior sessions.

RESULTS

Rasch analysis: The test data that are the subject of Rasch scaling analysis are first organized into a persons by items response matrix with binary cell entries (1/0) representing correct/incorrect responses to each of the items administered to individual respondents. In the present study, data provided by 178 respondents to subsets of the 280 test items were evaluated for fit to the measurement model. When data are found to fit the measurement model, the responses of persons to items are effectively additive. Moreover, there is indication that the items comprising a measurement system form a hierarchy along the variable which they share (i.e., sign recognition ability).

The joint maximum likelihood estimation (JMLE) procedure utilized in Rasch analysis to compute item difficulty and person ability estimates accommodates “incomplete” data designs (i.e., missing data are not problematic). That is because, for each of the person and item parameters to be estimated, there exist sufficient statistics (i.e., the *marginal* raw scores and counts of non-missing data observations). During the calibration process, the observed marginal counts and the observed and expected marginal scores are computed from the same set of non-missing observations. The item and person parameter estimates that are the *product* of Rasch scaling analysis enable the estimation of the outcome of any person-item interaction (present or missing) within the measurement frame of reference.

In the “real” world, data never accord with a statistical model exactly. To determine the extent to which data deviate from model expectations, Rasch scaling procedures rely upon mean-square fit analyses. These analyses are intended to identify *items* within a collection of stimulus materials that deviate seriously enough from model expectations that they distort or degrade a measurement system, as well as to identify *persons* whose test behavior contradicts the model. The removal of *specific* items and persons from the calibration analysis is a judgment call. In the end, the analytic goal is to determine if reasonable *adjustments* to the data produce a measurement system that operates according to the rules of arithmetic.

A mean-square fit statistic greater than 2.00 logits constituted the criterion value for the removal of items/persons from the final ASL-DT calibration. Accordingly, two of the 280 items included in the item collection were excluded from the item bank, resulting in a final set of 278 items. Similarly, the test records of three participants from the sample of 178 respondents were excluded from the final calibration analysis.

Figure 1 illustrates the distribution of difficulty (d_i) values (represented as *MEASURE* on the horizontal axis) for the 278 ASL-DT test items fitting the Rasch model. The item d_i are centered at 0.00 logit (observed $sd = 1.24$ logits). The distribution of difficulty of the stimulus materials comprising the ASL-DT item pool is essentially normal, with an effective operating range of -3.00 to +3.00 logits. The minimum observed d_i was -2.69 logits, and the maximum observed d_i was 5.19 logits (range = 7.88 logits).

For the 175 participants whose test records conformed to model expectations, the mean person ability (b_n) measure was found to be 0.64 logit ($sd = 0.72$ logit). The minimum observed b_n was -1.18 logits, and the maximum observed b_n was 2.86 (range = 4.04 logits). Figure 2 (right-hand panel) illustrates the distribution of b_n measured across the range of study participants. Like the item d_i distribution, the distribution of b_n is essentially normal. The d_i distribution is reproduced in the left-hand panel of Figure 2 to illustrate the extent to which the stimulus materials comprising the ASL-DT are targeted on the persons tested.

Reliability coefficients associated with Rasch scaling analyses take two forms. The person separation reliability (PSR) statistic indicates how well a set of test items can separate the b_n levels of the persons tested. The item separation reliability (ISR) statistic indicates how well the sample of persons tested can order the items in terms of their d_i values. Together, these two statistics are useful during the test development process in the review and refinement of item content to maximize the power of an assessment system to discriminate test-takers at differing b_n levels.

From the scaling analysis performed on the test records of 175 individuals who responded to subsets of the 278 ASL-DT items, the PSR was found to be .83. The ISR based upon the same data set was found to be .93. These statistics are expressed and interpreted in the same manner as standard reliability coefficients (i.e., correlations). As summary statistics, the observed PSR is very good, while the ISR is excellent. Together these indices confirm what is shown in Figure 2, namely that the study participants were, on average, relatively good signers, nonetheless exhibiting a wide range of ability. Finally, these statistics indicate that the ASL-DT is comprised of items spanning a wide range of difficulty, hence capable of testing persons across a broad range of ability.

Figure 1. Distribution of d_i values for ASL-DT items fitting the Rasch model.

Adaptive testing: Computerized adaptive testing has become commonplace in the social and behavioral sciences. Adaptive tests are intended to minimize the number of observations required for the measurement of a human characteristic or attribute, simultaneously maximizing the quality of information that is provided about individuals in the measurement process. In the present work, 35 self-administered ASL-DT adaptive test records were obtained. While the primary goal of the present work was to enlarge the database upon which the d_i calibrations were based, item calibration values based upon a smaller database in an

earlier phase of the R & D effort enabled the development of the ASL-DT adaptive testing software.

Figure 2. Map of ASL-DT item and person locations along the variable they share.

Across the 35 adaptive test records, the mean ability level of participants was found to be 1.96 logits ($sd = 0.99$ logit). The minimum observed b_n was -0.81 logit, the maximum observed b_n was 3.35 logits (range = 4.16 logits). Twenty of the 35 test records were provided by individuals who self-reported that they were “Able to Communicate Fairly Well.” The remaining 15 test records were provided by individuals who reported that they had “A Lot of Experience” or were “Fluent Signers” of ASL. Mean b_n on the adaptive tests for the former (i.e., intermediate level) group of persons was 1.64 logits ($sd = 1.02$). For the latter (i.e., advanced) group of persons, mean b_n was 2.39 logits ($sd = 0.78$). A comparison of these means yielded a statistically significant difference, $F(1,33) = 5.54$, $p < .05$. Thus, there is consistency between what is perceived and what is measured in terms of participants’ ASL proficiency level.

The average number of items administered in an adaptive testing session across the 35 test records was 27 (minimum = 10, maximum = 40). In 26 cases testing was terminated when items *remaining* in the bank lacked sufficient information (i.e., item appropriateness criterion was met). In the remaining nine cases, testing terminated when the test length limit was met (i.e., maximum items = 40). At this end of the b_n distribution, we expect the item appropriateness criterion to be the dominant reason for terminating a testing session.

On average, the standard error associated with the b_n measures for the 35 test records was found to be 0.43 logit. This translates to a reliability index = .82, comparable to the PSR of .83 observed for the larger sample of 175 persons tested. The largest observed standard error (for an individual test record) was 0.65, translating to a reliability index = .58. The lower

level of reliability observed here is entirely attributable to test length at termination (i.e., 10 items). The test records associated with this outcome were provided by fluent signers scoring at the extreme upper end of the b_n distribution, where standard errors will be at maximum value. The smallest standard error observed across the adaptive test records was 0.32, translating to a reliability index = .90. The test records relevant to this outcome were provided by test-takers whose b_n measures fell within areas of the d_i distribution populated with a sufficient number of items appropriate for administration.

Criterion validity: Table 2 shows mean performance in logits on the ASL-DT for each proficiency level. As expected, the intermediate proficiency group had significantly higher mean logit scores than the low proficiency group (planned comparison, $F(1,172) = 42.08$, $p < .0001$), and the high proficiency group had significantly higher mean logit scores than the intermediate proficiency group (planned comparison, $F(1,172) = 12.21$, $p < .001$). These proficiency group differences remained significant after adjusting for participant age, gender, race/ethnicity, and childhood SES (Low versus Intermediate Proficiency, $F(1,160) = 38.55$, $p < .0001$; Intermediate versus High Proficiency, $F(1,160) = 4.49$, $p < .05$).

Table 2. ASL-DT means in the logit metric, standard deviations (SE), and n's for ASL proficiency groups

Proficiency Group	Mean	SD	n
Low	0.11a	0.60	56
Intermediate	0.78a,b	0.57	92
High	1.24b	0.72	27

^a low vs intermediate, $p < .0001$.

^b intermediate vs high, $p < .001$.

Preliminary logistic regression analyses using ASL-DT logit scores as the predictor of proficiency group probability and participant age, gender, race/ethnicity, and childhood socioeconomic status as covariates revealed that after the ASL-DT scores were accounted for, only age made a significant contribution to group probability prediction. However, age accounted for less than 1.7% of the predicted variance. Therefore, only the ASL-DT logit scores were used in further analyses of proficiency group classification accuracy.

Figure 3 displays the ROC curves for group classification of the 175 individuals in the sample produced by discriminant analysis using the ASL-DT logit scores as the predictor. Table 3 displays the percentage of accuracy of classification, as indicated by the area under the ROC curves, sensitivity (proportion of true positives), and specificity (proportion of true negatives) for the high, intermediate, and low groups. The Self-Identified by Predicted classification matrix on the right displays the numbers of correct assignments and misassignments by the discriminant function.

The majority of low proficiency participants was classified as low proficiency (41 of 56). Intermediate proficiency participants were most often classified as intermediate proficiency, while misclassifications were spread broadly between the adjacent categories. High proficiency participants were most often classified as high proficiency. These results indicate that the ASL-DT most often classified participants into their self-identified proficiency category, and for the low and high proficiency categories, which permitted misclassification

over two proficiency steps, the ASL-DT placed the large majority of those participants within ± 1 proficiency group step from their self-identified group.

Figure 3. ROC curves for the ASL-DT logit measure.

Table 3. ROC statistics for the ASL proficiency groups.
(Accuracy = area under the ROC curve. Predicted Proficiency Group:
Group membership predicted by the discriminant function
based on ASL-DT logit scores)

	Proficiency Group			Actual Proficiency Group	Predicted Proficiency Group		
	Low	Intermediate	High		Low	Intermediate	High
Accuracy	82.30%	69.20%	74.50%	Low	41	11	4
Sensitivity	0.732	0.446	0.481	Intermediate	19	41	32
Specificity	0.798	0.759	0.889	High	5	9	13

Age of acquisition of ASL is related to ASL proficiency (DeKeyser, 2012; Krashen, Scarcella & Long, 1982; Newport, 2005; Uylings, 2006) and, unlike self-ratings of ASL proficiency, which are highly subjective and prone to personal bias, age of acquisition of ASL has the advantage of being a relatively objective, although crude, ASL proficiency proxy. Therefore, as convergent evidence that the ASL-DT scores were objectively related to ASL proficiency, we examined the correlation between age of acquisition of ASL and ASL-DT proficiency scores. These two measures were positively correlated ($r = .40$, $p < .0001$), tending to validate the ASL-DT as an ASL proficiency proxy measure.

Finally, we used multiple regression to predict the ASL-DT logit scores from the self-identified proficiency categories and age of acquisition jointly. Significant variance in the ASL-DT scores was accounted for by both Self-Identified Proficiency group ($F[2,170] = 22.71, p < .0001$) and age of acquisition ($F[1,170] = 9.22, p = .0028$), independently. The significant independent contribution of age of acquisition to the ASL-DT measure demonstrates that the ASL-DT captures additional, objective proficiency-related variance that is not captured by the subjective self-identified proficiency ratings alone.

CONCLUSION

The results of this study indicate that the data fit the Rasch model of person measurement very well. As illustrated in Figure 1, the test items span a wide range of difficulty (7.88 logits), with an effective range extending from -3.00 to +3.00 logits. Consistent with the distributions of items and persons shown in Figure 2, the PSR was very good and the ISR was excellent. These results indicate that the ASL-DT is capable of measuring sign recognition across a broad range of ASL ability.

Since no objective, independent ASL proficiency test is available to act as a criterion measure to evaluate the concurrent validity of the ASL-DT Rasch measure, the participant sample was divided into three groups based on self-assessment of their ASL ability. The three groups acted as a *prima facie* criterion measure to evaluate the ability of the ASL-DT to detect group differences in average ASL proficiency and to statistically classify individuals into proficiency groups. Discrimination among the three proficiency groups and the classification of individuals into self-identified proficiency groups in this chapter provides additional evidence of the construct and predictive validity of the ASL-DT Rasch measure.

Although the ASL-DT is a direct measure of learners' ability to discriminate phonological and morphophonological contrasts, the evidence presented in this chapter confirms that the test can serve as a proxy measure of ASL proficiency. The results presented here agree well with those of our previous validation study of the ASL-DT using an independent sample of participants and a greatly expanded item pool (Bochner et al., 2016). Bochner and colleagues (2016) used relatively objective sociolinguistic, academic, and job function criteria associated with different typical levels of lifetime ASL exposure to operationally define three different ASL proficiency groups. They showed that the ASL-DT displayed moderate to strong accuracy for classifying individuals into these objectively defined proficiency groups, and was substantially more accurate in correctly classifying individuals into proficiency groups than the most prominent subjective proficiency test (SLPI). Furthermore, the ASL-DT specifically outperformed the SLPI in its ability to discriminate between intermediate and high proficiency individuals. The present results regarding the ASL-DT's classification accuracy and its relationship to both subjective self-ratings and age of acquisition of ASL reinforce the conclusions of Bochner and colleagues (2016) regarding the relatively high accuracy of the ASL-DT as a proxy measure of sign language proficiency.

Furthermore, the nature of the discrimination tasks and how they relate to sign recognition, combined with data on intercorrelations among subskills comprising language proficiency (i.e., speaking, listening, reading and writing) and the factor structure of a

prominent language proficiency test (i.e., the internet-based TOEFL), support the contention that the ASL-DT can serve as an ASL proficiency proxy. As mentioned earlier, the ASL-DT is available at <https://apps.ntid.rit.edu/ASLRC/login/login.php>.

Chapter 13

THE EFFECTS OF CONVERSATIONAL PARTNER FAMILIARITY IN DEAF SIGNERS

Amanda C. Davis^{1,2} and Mary Lee A. Jensvold, PhD^{2,3,*}

ABSTRACT

The way in which an individual communicates changes based on various conversational aspects. Speakers adapt the form and content of their messages based on their judgments of what the listener knows and needs to know. Familiarity of a conversational partner affects verbal and nonverbal communicative behaviors. This is change in register, or language style, and is indicative of the ability to adapt to the listener. This study examined the effects of familiarity and the use of American Sign Language in deaf humans' conversational behaviors. Participants were deaf adults either living at or clients of a deaf assisted living facility. Participants were videotaped interacting with a conversational partner for 4 min each while playing a game. There were two conditions of trials: the partner was familiar versus unfamiliar to the participant. Two signing behaviors were measured: average duration of sign and reiteration of sign. All participants' duration of sign and reiteration of sign were significantly longer when interacting with an unfamiliar conversational partner. This research provides evidence for the linguistic aspects of ASL that are like spoken languages. These results add to research showing difference in conversational register in response to different types of partners.

INTRODUCTION

In face-to-face interactions, partners must initiate the conversation and then maintain it with constant adjustments and signals. For example systematic shifts in eye gaze, body posture, and head movements signal turn yielding behaviors (Duncan, 1972). With

* Corresponding Author Email: Jensvold@faunafoundation.org.

misunderstandings, partners repeat or revise appropriately (Brinton, Fujiki, Loeb, & Winkler, 1986; Brinton & Fujiki, 1991; Brinton, Fujiki, Winkler, & Loeb, 1986; Pearl, Donahue, & Bryan, 1981). Partners adapt the form and content of their messages based on their judgments of what listeners know and need to know.

Conversational partners are diverse, with variation occurring through differences in linguistic community, hearing ability, cognitive ability, age, status, or kinship. Partners make adjustment to these variations. In interactions with infants, caregivers often turn their statements into questions and use a higher-pitched voice (Schieffelin & Ochs, 1986). Speakers of Thai use different formality markers, pronominals, names, titles, and pragmatic particles depending upon their relationship to the listener (Iwasaki & Hori, 2001). Adults use politeness markers significantly more in conversation with their spouse than with a stranger (Premo & Stiles, 1983). Partners' coordination of function words such as prepositions and pronouns predicted whether the dyad would subsequently go on a date, which shows content reflecting interpersonal attitude (Ireland et al., 2010). Caregivers in nursing homes use slower speech rate and more variable pitch with elderly patients than with co-workers (Ashburn & Gordon, 1981). Also nurses used a higher pitched tone when speaking to patients at a nursing home versus a local hospital (Caporael, 2007). These adjustments also appear in young children when they simplify phrases and statements and use more variation in speech intonation while playing with inanimate objects such as a stuffed animal, and towards infant siblings (Dunn & Kendrick, 1982). Giles, Coupland, and Coupland (1991) reviewed a variety of behaviors such as utterance length, speech rate, vocal intensity, pausing frequency and length, gesture, posture, head nods, and facial affect that converge as speakers "adapt to each other's communicative behaviors" (p. 7).

One factor in interactions is the familiarity of the conversational partner. Across taxa, individuals react to strangers differently than to group members. A variety of species show individual recognition, including chimpanzees, fish, dolphins, birds, and wasps (see Tibbets & Dale, 2007 for review). Individual recognition also plays a role in group competition, dominance hierarchy, and mother/infant relationships across taxa (Tibbets & Dale, 2007). Social relationships with familiars can include a high degree of touching in both humans and nonhumans (Marler, 1976; Mehrabian, 1968). Humans stand closer to familiars than strangers regardless of crowd density (Burgess, 1983). Yet behaviors with strangers also can be quite aggressive. Chimpanzees show aggressive displays to neighboring chimpanzees, sometimes with fatal attacks (Goodall, 1986). Aggression among humans, particularly between separate groups, fills news stories daily. Humans and nonhumans react differently to familiars than strangers.

Systematic studies with humans have explored variation in general behavior based on familiarity. Among children, play in familiar dyads contained more social behaviors than in unfamiliar dyads (Doyle, Connolly, & Rivest, 1980). Lederberg, Ryan, and Robbins (1986) compared play among deaf, hearing, familiar, and unfamiliar dyads of children. Hearing children used more gestures, exaggerated facial expressions, and vocalizations with familiar than unfamiliar deaf partners. Deaf children used more pretend play and touching with familiar than unfamiliar hearing partners. Adults with Down syndrome showed differences in non-verbal behavior and body mobility with familiar versus unfamiliar partners (Leudar, Fraser, & Jeeves, 1981).

Researchers also have examined differences in speech during interactions with familiar versus unfamiliar partners. Children in familiar dyads exhibited significantly more

conversations, relevant utterances, and longer utterances than children in unfamiliar dyads (George & Krantz, 1981). Chisholm and Pitcairn (1998) examined conversational differences between friends and nonfriends in an established group. Exclusive utterances were utterances that were not directed toward or excluded an individual, and they were more frequent between nonfriends. Inclusive utterances were utterances that were directed towards or inclusive of an individual, and they were more frequent between friends. Another study examined children's responses to a misunderstanding with an adult interlocutor who was either an unfamiliar or the child's mother. Children used a larger number of lexical items in their speech revisions with unfamiliar than with their mothers (Tomasello, Farrar, & Dines, 1984). As adolescents individuals asked less direct questions to unfamiliar than familiar partners (Turkstra, 2001). Adults with cochlear implants were more likely to interrupt and use a loud voice with unfamiliar than familiar partners (Tye-Murray, Witt, & Schum, 1995).

ASL uses space and three-dimensional movement, and this can be measured in multiple ways. As spoken languages are broken down into series of vowels and consonants, ASL's sequential units are holds and movements. Holds are when the sign is held in place, and movements are when the sign is in motion (Liddell, 1984). Researchers have measured holds and movement using video analysis (Wilbur, 2009). For example Johnson and Liddell (2011) measured the period of time when the hand was moving. A lexical database of ASL described information, including duration, on nearly 1,000 signs (Caselli, Sehyr, Cohen-Goldberg, & Emmorey, 2017).

Variations occur in sign production for a variety of reasons. For example there are regional accents or dialects. American signers from Philadelphia sign differently than signers from other parts of the United States (Porzucki, 2015). The signs of Philadelphia signers retain ASL's historical roots to French Sign Language. Signers from different regions in Britain use different variations of colors and number signs. In that study variations in signs also occurred between different age groups (Stamp et al., 2014). African American signers in the United States use a larger signing space, and change form based on the audience (Sellers, 2012; McCaskill, Lucas, Bayley, & Hill, 2011). Demographic differences, identity, age, and the individual's familiarity with his or her signing partner also influence the way in which signers articulate signs (Valli & Lucas, 2000; Zimmer, 2000; Sutton-Spence & Woll, 1999).

In speech there is evidence that social settings and partners produce shifts in register. In signers there is less evidence for register shifts in response to partners. The objective of the current study was to investigate register shifts in ASL. Specifically it compared duration of signs and reiteration of signs in human interactions with familiar versus unfamiliar signing partners. The hypothesis was that the average duration of signs and number of reiteration of signs would increase from familiar to unfamiliar conversational partner conditions.

METHODS

Participants

Participants were recruited from the Chestnut Lane Assisted Living Community (CLALC) in Gresham, Oregon, USA. CLALC provided assistance and personal care for deaf individuals of all ages and their families. ASL was the predominant mode of communication.

As an assisted living facility, CLALC offered personal services and assisted care to support independence and privacy, while serving the unique needs of deaf residents. Participants volunteered via sign-up sheets posted on the community bulletin board. Participant recruitment began before data collection started and continued after trials began. Participation in this study was open to all ages and sexes who were fluent in ASL.

There were a total of 10 participants. Two participants were excluded from analysis due to filming error, yielding a total of 8 participants for analysis. All participants were between the ages of 20 and 58. There were two males and six females, and all were residents and/or clients of CLALC. They all signed a consent form. This study received approval from Central Washington University's Human Subjects Review Committee (H11079).

Conditions

Each participant participated in two separate trials on two separate days. During a trial the participant interacted in one of two conditions; either with a familiar or an unfamiliar interlocutor.

The familiar interlocutor was the director of CLALC (SA) and was the only interlocutor in the familiar condition. SA was familiar with each resident, fluent in ASL, and interacted regularly with members of CLALC.

The unfamiliar interlocutor was someone the participants had never met before, had never been to CLALC, and was the only interlocutor in the unfamiliar condition. This interlocutor was recruited from Portland State University's (PSU) advanced ASL classes and recommended by the instructor of that class. The interlocutor took an assessment of ASL fluency including vocabulary and modulation tests, and an interview with the PSU ASL instructor.

Materials

The participant and the interviewee played the board game *Guess Who?* during each trial. *Guess Who?* was a board game in which two players tried to deduce the identity of their opponent's mystery person. Players asked each other yes/no questions that helped narrow the pool of possibilities. In this game through process of elimination, the identity of the mystery person becomes evident. This game elicited descriptive categories of glosses such as MAN, WOMAN, BLONDE, and BRUNETTE. Thus many of these glosses occurred repeatedly throughout all trials. This provided data for a comparison of glosses between the familiar and unfamiliar condition. A video camcorder recorded the 4 min trials.

ASL is translated to English by using a gloss. A gloss is the written word for word translation from one language to another, and in the case of ASL is also used in notating a sign's facial and body grammar (Hanson & Bellugi, 1982). For example, a gloss for the word "tree" would be TREE. In this chapter glosses appear with all capital letters. Glosses are distinct from signs; the sign is the action while the gloss is the name for the action.

Procedure

Trials occurred at a table in the reading room at CLALC. The reading room was a common area where residents often read books or played games. The experimenter (AD) arranged the game and camera before trials began. The camera was angled to ensure that the participant was visible in the frame.

AD asked participants to sign up for two trials within the same week. Participants were not aware of the order of the presentation of conditions until they participated in the first trial. The order of presentation of conditions for each participant was randomly assigned. There were a total of 16 trials, two for each participant analyzed in the study.

When a participant arrived for his or her first scheduled trial, AD obtained verbal consent to turn on the video camera and begin recording. This was done to establish that the participant was comfortable in front of the camera. AD then discussed with the participant the procedure of the trial.

AD explained to participants that they would meet with an interlocutor and play a game of *Guess Who?* for 4 min. AD asked participants if they had any questions before the interaction began and explained that they were welcome to ask questions at any time. AD instructed that if the game was finished before the end of the 4-min trial, the interlocutor and participant should start another game. AD left the room after the trial began. AD timed each trial on a stopwatch, and entered the room after 4 min to notify participants that the trial was over and to stop the recording. Then AD reminded the participant of the date and time of the second trial. If it was the second trial, participation in the study was complete.

Data Selection

AD transcribed all video footage for each participant. When AD observed a sign on the video, she extracted a video clip of the sign and saved that footage into a separate file. The 3 s before and after the sign occurred were included in the video clip. The beginning of a sign was defined by the time the hand(s) began moving, and the end of a sign was defined as when the hand(s) moved out of the sign formation or until the hand(s) set to rest. Each video file had a label that represented the participant with a code, the gloss, and a number representing the condition to ensure coders were blind to the condition. A total of 311 video clips were compiled of all signs that occurred in each condition for all participants.

To obtain video transcription reliability, another coder who is fluent in ASL viewed 20% of the total video data and transcribed it. Agreement between AD and the second coder was 92%. For all video clips where AD and the second coder disagreed, the two coders viewed the clips together to agree on a gloss.

From the transcript AD made a list of each participant's glosses in each condition. From this list for each participant, AD selected glosses that occurred in both the familiar and unfamiliar conditions for analysis and subsequent comparison. For example, if a participant signed YES BOY in the familiar condition and signed BOY NO in the unfamiliar condition, AD selected BOY for analysis. Another participant may not have signed BOY and instead may have signed GIRL in both conditions. In that case, AD selected GIRL for analysis. If a gloss only occurred in one condition, it was excluded from analysis for that participant. This selection process yielded 17 glosses which were BALD, BEARD, BLACK, BROWN, EYES,

GIRL, GLASSES, HAIR, HAT, HAVE, MAN, NAME, NO, PERSON, WHITE, WOMAN, and YES. Then AD selected all the video clips that contained signs of these glosses. This resulted in 205 video clips of signs. Table 1 shows the glosses for each participant and the number of times glosses occurred in each condition before the selection.

Data Coding

Sign Duration

A coder (LW) viewed each video clip of a sign and recorded the start and end of the sign to the nearest tenth of a second. The start of a sign was when the signer's hand or hands begin moving to form a sign. The end of a sign was when the signer's hand or hands changed from the sign's configuration or moved to a resting position. LW had the option to watch a clip as many times as needed to record the correct time. LW had a one-term classe in ASL training, and an additional 2 years of experience using ASL.

To test for interobserver reliability in sign duration a second coder coded 20% of the total data, which was 41 video clips. This coder had a one-term class in ASL, and 5 years of experience using ASL. The interobserver agreement for the start of a sign was 94% and for the end of a sign was 91%.

Sign Reiteration

Gardner, Gardner, and Drumm (p. 47, 1989) defined reiteration of a sign as the same sign recurring immediately within a single utterance. For example, a participant may form the sign BOY or may reiterate the sign BOY BOY BOY. This definition was used to record the number of times a sign of the same gloss occurred within a clip. AL recorded how many times a sign was reiterated in each clip. AL had the option to watch each clip as many times as needed to record the correct number of reiterations.

Table 1. Number of signs of each gloss for each participant

Participant	Gloss	# of Video Clips	
		Familiar Condition	Unfamiliar Condition
P ₁	EYES	1	1
	GLASSES	1	1
	HAIR	1	1
	HAVE	2	2
	NO	3	5
	PERSON	1	2
	YES	2	1
P ₂	BALD	1	1
	BLACK	1	3
	GIRL	1	1
	GLASSES	1	1
	HAIR	1	4
	HAT	1	2
	MAN	1	1
	NO	4	5
	YES	2	5

Participant	Gloss	# of Video Clips	
		Familiar Condition	Unfamiliar Condition
P ₃	HAT	1	1
	HAVE	3	4
	NAME	1	3
	NO	5	2
	YES	1	2
P ₄	HAIR	1	1
	HAT	1	2
	NO	2	3
	YES	3	4
P ₅	BEARD	1	1
	GLASSES	1	1
	HAVE	2	5
	NO	1	1
	PERSON	4	3
	YES	3	4
P ₆	BALD	1	1
	GLASSES	1	2
	NO	4	5
	WOMAN	2	1
	YES	4	3
P ₇	BROWN	1	1
	GLASSES	3	4
	HAIR	2	1
	NO	1	1
	PERSON	5	4
	WHITE	1	2
	YES	1	2
P ₈	GLASSES	1	1
	HAT	1	2
	HAVE	3	1
	NO	3	4
	WOMAN	2	2
	YES	1	3

To test for interobserver reliability a second coder coded 20% of the total data, which was 41 video clips. The interobserver agreement for repetition of a sign was 94%.

Data Analysis

The analysis required an equal sampling of each sign in each condition for each gloss for each participant. In many cases, participants produced an equal number of signs for each gloss. For example, P₁ signed EYES one time in each condition. In other cases, a participant signed a gloss an unequal number of times in each condition. For example, P₁ signed NO three times in the familiar condition and five times in the unfamiliar condition. In this case

AD randomly selected three video clips from the unfamiliar condition. This ensured an equal number of video clips of the gloss NO in each condition. A total of 88 video clips remained for comparison, 44 in each condition.

A paired sample t-test compared the mean duration of signs between conditions. The confidence interval was set at 95%. A paired sample t-test compared the mean number of reiterations of signs in each condition. The confidence interval was set at 95%.

RESULTS

Table 2 shows the average sign duration in each condition for each participant. Signs had significantly longer durations in the unfamiliar condition ($M = 1.2$ seconds, $SD = .39$) than the familiar condition ($M = .88$ seconds, $SD = .24$); $t(7) = 2.542$, $p = .0386$.

Table 3 shows the mean number of reiterations in each condition for each participant. Participants reiterated signs significantly more often in the unfamiliar condition ($M = 2.41$, $SD = .97$) than the familiar condition ($M = 1.63$, $SD = .43$); $t(7) = 2.607$, $p = .0351$.

Table 2. Average Duration of Signs in Seconds

Participant	Familiar Condition	Unfamiliar Condition
P ₁	1.1	1.2
P ₂	1.3	2.0
P ₃	0.9	0.6
P ₄	0.6	1.3
P ₅	0.8	1.0
P ₆	0.8	1.1
P ₇	0.9	1.1
P ₈	0.6	1.1

CONCLUSION

The conversational behaviors of the participants in this study were influenced by familiarity of the conversational partner in a predictable direction. Individual signs were longer in duration and reiterated more often in the familiar condition than in the unfamiliar

condition. Just as speakers adjust their speech to various conversational partners (Chishold & Pitcarn, 1998; Iwasaki & Hori, 2001; George & Krantz, 1981; Tomasello et al., 1984; Tye-Murray et al., 1994), the signers in this study adjusted their signs to the various partners. This study focused on two types of differences, speed and reiteration, which are part of the larger body of pragmatic devices used in register.

Duration of Sign

The mean duration of signs was significantly greater when participants were interacting with unfamiliar signing partners. Some participants produced signs up to two times longer when conversing with an unfamiliar than with a familiar partner. For example, P₄'s average duration of signs with a familiar was 0.6 sec, and with an unfamiliar it was 1.3 sec. Wilbur (2009) asked signers to recite a narrative at slow, medium or fast speed. The average sign duration was 0.66, 0.51, and 0.42 s respectively. In this study the average duration for unfamiliar was 1.2 s and for familiar was 0.88 s. The sign durations in this study were within the range of durations in Wilbur's study.

Listener's understanding and memory of speech is highly dependent on speech rate (Blau, 1990; Small, Kemper, & Lyons, 1997). Deterioration in speech comprehension occurs at around 200-250 words a min (Carver, 1973; Foulke, 1968; Griffiths, 1990). Deterioration in sign comprehension occurs at 2.5-3 times the normal signing rate (Fischer, Delhorne, & Reed, 1999). In Wilbur (2009) faster signing occurred with decreased sign duration and changes in pauses. Pauses were fewer and had decreased durations than in normal and slow signing conditions. Future analysis could explore length and number of pauses in face-to-face interactions such as the method used in this experiment.

Reiteration of Sign

Overall reiterations occurred significantly more often with unfamiliar than familiar partners. Some participants reiterated signs up to two times more often with unfamiliar than familiar partners. For example, P₂'s average reiteration of signs was 1.6 times in the familiar condition and 4 times in the unfamiliar condition.

Reiteration of a spoken word is one of the first learned conversational devices for children, and one of the last lost for adults (Johnstone, 1987). Speech is easier to understand when it includes reiteration of words (Fan, Yu, & Jiang, 2009). Reiteration increases comprehension in second language learning (Cabrera & Martinez, 2001; Weinstein-Shr, Cervantes, & Gainer, 1992; Pica, Young, & Doughty, 1987), and parents reiterate words to help with their child's language development (Keenan, 1975; Snow, 1972). Reiteration in speech increased comprehension in adults with Alzheimers (Small, Kemper, & Lyons 1997) and aids second language comprehension (Cabrera & Martinez, 2001). Therefore, reiteration makes communication more effective. Study of spontaneous oral narrative shows that reiteration is used to bring attention to certain themes and offer relevance to proceeding discourse for partners (Ochs, 1979; Shepherd, 1990). This may be especially true when conversing with an unfamiliar partner, and playing a game involving a deductive reasoning

structure. Reiterating signs may make the signs more comprehensible to an unfamiliar partner.

Speed of signs and reiteration are two communicative aspects that change register in conversations. Emmory, Gertsberg, Korpics, & Wright (2009) asked participants to vary signs production in experimental conditions. In one condition participants were instructed to “shout” and in another to sign informally (e.g., “sloppy”). In the normal condition they were instructed to use standard signing. Signers used a smaller signing space and signs were of shorter duration in the informal condition than in the shout or normal conditions. These finding support those of this study. Emmory et al. were able to vary register experimentally in artificial conditions. The current study created systematic natural conditions and also found decreased duration in one condition. Both informal and familiar conditions in these two studies produced decreased durations. Often speakers and signers use an informal register with familiar partners and this research support that.

Future research could explore other aspects of register such as pauses (Wierzbicka, 1985; Wilbur, 2009) and politeness markers (House & Kasper, 1981; Meyers, 1991). Politeness and addressing the partner with titles is more predominant when individuals are speaking with strangers than with familiars (Mills, 2003). For example, in English when greeting someone in a formal setting, it is proper to use the pronoun Mr. or Mrs. There also may be markers for politeness in signed languages with strangers. It is polite in deaf culture to make eye contact while communicating (Isreal, Cunningham, Thumann & Arnos, 1992). This could be studied systematically. There may longer eye contact between strangers meeting for the first time in comparison to close friends.

All participants of the current study lived in an assisted living center (CLALC). There are differences in communication of individuals that are community versus institutionally housed (Brinton & Fujiki, 1993); communication is limited in scope, variety, and quantity within institutional settings (Lubinski, Morrison, & Rigrodsky, 1981; McLean, Brady, & McLean, 1999). Daily social activities also are affected by living condition. When compared to individuals living independently with similar mental and physical impairments, residents of assisted living facilities engage in significantly more community activities because they are easily available to them (Mausbach, Depp, Cardenas, Jeste, & Patterson, 2008). There is a sense of community that occurs within the facility; therefore, it may affect the way that individuals communicate with strangers. An area of future research may be comparing responses and sociality of community versus institutionally based individuals under the same conversational conditions.

This research provides evidence for pragmatic aspects of ASL. This study shows differences in sign register with different partners and adds to an area of research that deserves further investigation. These discoveries are only possible with the study of face-to-face interactions (Pickering & Garrod, 2004). Though this study is the first of its kind to be conducted within a deaf human population, its results are important in emphasizing the parallel between signed and spoken languages in terms of different factors that influence the way in which an individual adjusts to the partner.

Chapter 14

USING WRITTEN ENGLISH IN THE AMERICAN SIGN LANGUAGE CLASSROOM

Jason Listman* and Kalyna Sytch

National Technical Institute for the Deaf at Rochester Institute of Technology
Rochester, NY, US

ABSTRACT

In the field of American Sign Language (ASL) pedagogy, the most popular teaching method seems to be the Direct Experience Method (DEM) (Newell, Mallery, Menkis, Holcomb, & Arthur, 1980). DEM encourages teachers to use ASL with the support of pictures, mime-pantomime, objects, and/or scenarios to teach vocabulary, language structure, and concept rules. Advocates of DEM discourage using English as a learning tool in the classroom. Studies in the field of second-language acquisition (SLA) show mixed results; some claim that only the target language should be used in the classroom while others argue that some use of the first language (L1) in the second language (L2) classroom helps students learn better (Cook, 2001; Van Lier, 2000). This study compared DEM with a modified DEM that includes written English as a learning tool to see which approach is more effective. The results suggested that the participants taught through DEM with written English support outperform those who are taught strictly with DEM and no written English. This study can help teachers understand the potential benefits of using minimal amounts of a student's native language in L2 classrooms. Limitations and recommendations for future studies are also highlighted in this chapter.

INTRODUCTION

Teaching and learning American Sign Language (ASL) as a second language (L2) has become very popular within the past couple of decades throughout the United States and parts

of Canada. In 2015, the Modern Language Association reported that ASL is now the third most studied L2 at colleges and universities in the United States (MLA, 2015). Public high schools offer ASL as a second language (Rosen, 2008). Students enroll in ASL classes for different reasons. Some are interested in becoming ASL-English Interpreters (Peterson, 2009), teachers of the Deaf, social workers, speech-language therapists, or audiologists (Quinto-Pozos, 2005). Some students take ASL to satisfy a foreign language requirement, and others are simply intrigued with ASL and want to learn to communicate with the North American Deaf community.

Clearly, the ASL field is growing rapidly, particularly for L2 teaching and learning. Even with the growth of ASL teacher training programs, courses offered in ASL, and ASL teachers working in the field, not much is known about the acquisition of ASL as an L2. There has not been much dialogue between ASL researchers and educators, and teachers of other foreign languages (Quinto-Pozos, 2005). Second language acquisition (SLA) theory and research have focused on the acquisition of spoken and written languages, paying little, if any, attention to sign languages. Engaging in research concerning ASL as an L2 is especially challenging because of the few ASL tenured and tenure-track positions available in American higher education (Quinto-Pozos, 2005). Most ASL teachers are practitioners, and are not trained to conduct ASL research. Research related to sign language is mostly on interpreting, linguistics, and Deaf education. There are only a few ASL studies that focus on the effectiveness of teaching methods and strategies for L2 learners (Bussion, 2007; Radford, 2012; Rosen, 2015).

For many years, teachers and scholars have debated the best method for teaching students the grammatical structures of an L2 (Cook, 2001; Ellis, 2006). One of the more common teaching methods, the Direct Method (Richards & Rodgers, 2014), advocates the use of only the target language to teach grammar rules inductively. However, the most recent teaching methods seem to support using minimal amounts of a student's first language (L1). In other words, it is acceptable to use some native language as a learning tool to teach L2 grammar (Cook, 2001; Turnbull, 2001). SLA literature shows mixed results; some studies claim that, in the L2 classroom, the target language should be used exclusively, while others argue that discretionary use of the native language will help students learn better (Cook, 2001; Turnbull, 2001).

Currently, in the field of ASL pedagogy, the most popular method is the Direct Experience Method (DEM) (Newell, Mallery, Menkins, Holcomb, & Arthur, 1980), which is very similar to the Direct Method (DM) approach. DEM encourages teachers to use pictures, mime-pantomime, real objects, and/or scenarios to teach vocabulary, language structure, and concept rules. Advocates of DEM disapprove of using English as a medium of instruction in the classroom, (Quinto-Pozos, 2011) with no strong empirical evidence regarding the effectiveness of the method (Rosen, 2010). Instead, instruction seems to be influenced by the teacher's intuition and cultural beliefs.

The American Council on the Teaching of Foreign Languages (ACTFL) released a position statement encouraging language teachers to use the target language 90 percent of the time (2010). There is a clear consensus that use of the native language, in this case English, is highly discouraged. However, SLA research has not empirically examined this belief. Clearly, research is necessary to examine teaching methods and strategies that help L2 learners learn ASL effectively.

Use of English in Language Teaching Methods: Some teaching methods and approaches support the use of a student's native language in the classroom, while others do not. For the purpose of this chapter, only two teaching methods will be discussed, the Grammar Translation Method and the Direct Experience Method. The earliest recognized teaching method is known as the Grammar Translation Method (Richards & Rodgers, 2014). This method was the most popular teaching method in the early 19th century. The Grammar Translation Method advocates for the use of the native language as a medium for instruction, where students engage in translation exercises, such as translating vocabulary and sentences from the target language back into their native language. Grammar is also taught deductively, where teachers purposefully teach grammar in isolation. Reading and writing are the main focus of this teaching method, with little to no attention given to improving learners' face-to-face communication skills. Richards and Rodgers (2014) criticized this method for its lack of attention to face-to-face communication.

Critics of the Grammar Translation Method developed their own teaching method which is known as the Direct Method in the early 20th century. (Some refer to this method as the Natural Method.) The Direct Method theorizes that teaching an L2 should be like learning an L1—a monolingual approach (Richards & Rodgers, 2014). The Direct Method discarded using students' native language in the classroom in favor of using only the target language as the medium of instruction. Advocates of this method teach grammar inductively. The ultimate goal is to focus on building communication through face-to-face interaction, spontaneous use of language, no use of translation, and little explicit attention to grammar rules. However, critics of this method argue that teachers often go to great lengths to avoid using the native language when students could learn more efficiently if the teachers used their native language to teach simple and brief concepts (Richards & Rodgers, 2014). Moreover, the Direct Method can be difficult to apply in a classroom setting due to class size and time limits.

Since the emergence of the Direct Method, most teaching methods encourage teachers to avoid using a student's native language. However, the most recent teaching methods allow cautious use of the L1 in the classroom. These include communicative language teaching approaches and task-based learning methods; however, the theoretical foundations of these methods do not provide clear examples of when the native language can or should be used (Cook, 2001). Except for the Grammar Translation Method, which has little to no support in current literature, most teaching methods discourage using the native language.

Research on the Use of Students' Native Language in the L2 Classroom: In the field of SLA, research studies suggest that there are some benefits to using the L1 as a bridge for students to learn an L2 (Cook, 2001). Two large-scale studies compared the Explicit Method and the Implicit Method to examine which method was more effective (Levin, 1972; Hammond, 1988). The first study was conducted in Sweden by Levin (1972), with grammatical explanations provided in L2 English in some cases and in L1 Swedish in others. The study found that adult learners in the Explicit Method group, where they were instructed on grammar functions using their L1, performed better than those who learned through the Implicit Method where L1 was not used. However, in another comparative study, Hammond (1988) found that those taught grammar inductively through the Natural Approach did better than those taught deductively using a modified Grammar Translation Method. There were some limitations to the above-mentioned studies, however. For example, Ellis (2012) identified some methodological weaknesses with comparative studies, including lack of control groups and no attention to student's learning styles. Also, some of the comparative

studies were taught by different teachers. Regardless of the limitations, the comparative studies provide some evidence that the L1 can be useful for learning an L2. (See Ellis, 2012 for review of comparative studies regarding teaching methods.)

Based on survey reports from teachers and students, using the L1 in the classroom contributes to the learning process in a variety of contexts (Tang, 2002); however, excessive use is not encouraged because students will become too dependent on translating the language into their L1 (Atkinson, 1987). Some studies have shown that starting with the L1 at the beginning of class provides a sense of security and validates the learners' experience, allowing them to express themselves (Schweers, 1999). Similar results have been reported in English as a Second Language (ESL) and English as a Foreign Language (EFL) classes among Chinese (Tang, 2002), Greek (Prodromou, 2002), Croatian (Duimovic, 2007), Spanish (Schweers, 1999), and Iranian (Nazary, 2008) students. Teachers may also use the L1 to explain grammar, give instructions, help students, and provide correction (Atkinson, 1987; Cook, 2001). Motivation is another reason why teachers may use the L1, such as helping struggling students understand complicated grammatical structures (Duff & Polio, 1990). Using the L1 can be more efficient than encouraging students to guess through visual materials (Cook, 2001). Moreover, using the L1 enables teachers to build better rapport with their students (Nation, 2003). Teachers may also use code-switching to clarify and check for a student's comprehension. It is clear that there are advantages to judiciously using a student's L1 to support L2 learning in the classroom.

There are a few studies that examined the use of English as a tool to effectively teach ASL (Bussion, 2007; Rosen, 2010). A study by Bussion investigated whether having ASL gloss helped beginners improve their ASL grammatical knowledge. The results showed that, not only did the students' ASL grammar improve, their English grammar improved as well. This may be a result of their comparing English with ASL, thus becoming more knowledgeable in both languages (Bussion 2007). Rosen, DeLouise, Boyle and Daley (2014) compared Voice-Off and Voice-On approaches in the classroom, and found that students in a Voice-Off ASL classroom did significantly better than students in a Voice-On classroom. However, a third experiment showed that students with learning disabilities did equally well in Voice-Off and Voice-On groups, depending on their visual and verbal abilities.

There is a widespread assumption that use of a student's L1 will interfere with their learning (Atkinson, 1987; Cook, 2001). Cook (2001) argues that scholars and practitioners need to reexamine this notion. Cook theorizes that L2 learners cannot be taught as if they are learning their first language. Adult language learners are beyond the critical period for language acquisition, and therefore they typically do not have the neural plasticity that allows effortless acquisition of language knowledge and structure due to incidental exposure to the target language. Cook also argues that the L2 brain is an interlanguage brain, and there are not two separate compartments for the grammar systems of both languages. Instead, both languages are interwoven in the L2 learner's mind. The meanings of words in the L2 do not exist separately from meanings in the L1. The L2 student has the capacity for code-switching, where both languages are simultaneously online. Following Cook's reasoning, in the case of ASL and English in the classroom, it is impossible to eliminate English entirely; the ASL learners are already critically examining ASL with their use of English in their minds.

Purpose: Despite evidence that using the L1 in the classroom can be effective in supporting second language acquisition, many studies claim that exclusive use of the L2 enhances a student's learning of the target language (Cook, 2001; Turnbull, 2001). More

research is needed to understand the effect of L1 use in the L2 language classroom. This chapter reports results of a study designed to examine whether using written English as a learning tool helps L2 ASL learners to acquire ASL effectively. We hypothesized that students who are taught through DEM with written English support would outperform those who were taught using DEM only.

This experiment compared two teaching methods for adult L2 learners who are at beginning levels of ASL ability. Participants were randomly assigned into two groups, and results from the two groups were compared. The control group (*ASL+Pictures*) watched a lesson taught using the Direct Experience Method (DEM) with no written English on any teaching materials. The treatment group (*ASL+English*) watched a lesson taught using DEM with written English as a learning tool. The study examined learners' ability to recognize the grammaticality of ASL "if-then," conditional, statements. As part of the study, a survey was administered to collect participants' opinions about using English as a learning tool both inside and outside of the classroom.

METHOD

Participants

A total of 52 ASL students participated in this study. The participants were full-time undergraduate students enrolled at Rochester Institute of Technology (RIT) and were paid for their participation. RIT includes the National Technical Institute for the Deaf (NTID) as one of its nine colleges, with approximately 1,200 deaf and hard-of-hearing students on campus. Consequently, hearing students are regularly exposed to ASL in classrooms, dorms, and clubs across the campus. Participants were all recruited from ASL courses at RIT offered through the College of Liberal Arts. All participants in the study identified as Hearing or Hard of Hearing, spoke English fluently, and were either currently taking Beginning ASL I, Beginning ASL II, Intermediate ASL I, or had taken these classes in the past. Participants ranged in age from 17 to 52 years ($M = 21.3$ years, $SD = 6.3$). Demographic information from the participant sample is displayed in Table 1.

Table 1. Demographics for D/HH and Hearing participants. (* $p < .05$)

Measure	Level	Group			
		ASL with English (N = 27)		ASL with Pictures (N = 25)	
		M	SD	M	SD
Age		21.3	6.3	21.6	5.2
		%	N	%	N
Gender	Men	48.2	13	28.0	7
	Women	51.9	14	72.0	18
		%	N	%	N
ASL Level*	Beginning I	33.3	9	16.0	4
	Beginning II	59.3	16	52.0	13
	Intermediate I	7.4	2	32.0	8

Instrumentations and Materials

To measure whether the treatment had an effect on participants' learning, the research team, consisting of ASL teachers and research assistants, developed a Grammaticality Judgment Test (GJT). Grammaticality judgment tasks are among the common instruments for assessing L2 learners' linguistic ability in second languages (Ellis, 1991). A GJT consists of both grammatical and ungrammatical sentences, and evaluates learners' knowledge of syntactic structures. For the purpose of this study, twenty ASL conditional sentences were created. Students had to choose whether the stimulus sentences they saw were grammatical or not. Ten of the sentences were grammatically correct whereas the other ten were incorrect. All 20 sentences had correct ASL word order, but the non-manual markers were altered for the incorrect sentences, thus making them grammatically incorrect. In the correct conditional sentences the signer raised his eyebrows and leaned his head forward while producing the conditional clause. Immediately after expressing the conditional clause, the signer returned to a typical facial expression. For the incorrect sentences in the GJT, the signer did not raise his eyebrows or lean forward during production of the conditional clause.

All sentences were signed by the same native male signer, an ASL teacher. The native signer was asked to record each statement three times with the supervision of a fluent ASL instructor who directed the recording session in a studio with proper lighting and background. The 20 sentences were embedded into one of two surveys created on SurveyMonkey, an online, cloud-based, survey development platform. The sentences were viewed by participants in random order.

To ensure the clarity of each sentence, a pilot study was conducted with five ASL-English interpreting students before finalizing the GJT. The five participants were asked to take the GJT and provide feedback on whether the sentences were clear to them. Based on the feedback received from the interpreting students, the research team modified a few sentences to enhance clarity.

Survey

Participants' opinions and attitudes on the use of English in the ASL classroom were also collected in a survey. The survey questions were modified versions of questions based on Al Sharaeai's (2012) surveys from her unpublished master's thesis. The first subsection of the opinion survey asked participants to rate how often they use English inside and outside of the ASL classroom using a Likert-scale (1 = *Never*, 4 = *Always*). The second subsection had ten statements asking participants' opinions about the use of English in the ASL classroom using similar Likert scale (1 = *strongly disagree*, 5 = *strongly agree*). The third subsection had ten statements, and asked for participants' opinions on teaching methods using another Likert scale (1 = *strongly disagree*, 5 = *strongly agree*).

Lessons

The experiment included two video lessons on conditional statements. A native ASL user, a Deaf female ASL teacher from NTID, recorded the two lectures and was compensated

for her time. The first lecture, designed for the *ASL+Pictures* group, used slides with pictures to teach conditional sentences through the Direct Experience Method. The second lecture, designed for the *ASL+English* group, used slides with pictures, written English, and ASL gloss explaining the conditional sentence structures. Both lessons were digitally recorded in a studio at RIT with proper lighting and background. The lessons were approximately two minutes long. Each video lesson had a split screen; the screen on the left showed the ASL instructor explaining the conditional structure, and the screen on the right contained PowerPoint slides of the lesson itself. The videos were uploaded to YouTube as unlisted and were inserted into SurveyMonkey.

Procedure

Prior to the experiment, each participant viewed a two-minute vocabulary video. Participants were required to watch the video and ascertain if they understood more than half of the vocabulary before they could join the experiment. This was done to ensure that participants would understand the vocabulary used in the GJT. Testing was conducted in an interpreting lab at RIT. Participants were recruited from classes and came individually to watch one of the two lessons and take the GJT. When the participants arrived at the interpreting lab, they were randomly assigned into one of the two groups and then began by completing a demographic questionnaire.

A pretest was administered to collect a baseline measure of the participants' knowledge and understanding of conditional statements. They were asked to sit and watch twenty sentences and respond whether the sentences were correct or incorrect. They also had the option to respond "I don't know."

After completing the pretest, both groups watched a short, two-minute lesson. After watching the lesson, participants took the posttest, comprised of the same 20 sentences as the pretest, but the video clips were in a different random order. Again, they had to decide whether the sentences they saw were signed correctly or incorrectly.

One to two weeks after taking the pretest and posttest, participants returned to take a delayed test and to complete a survey regarding their opinions and attitudes on the use of English in the ASL classroom. The delayed test consisted of the same 20 sentences in random order. The delayed test measured the ability of participants to retain the knowledge they had gained from the mini lesson taken during the first session.

RESULTS

Posttest minus pretest difference scores (Immediate Learning) and delayed test minus pretest difference scores (Delayed Learning) were computed for each participant to capture the improvement in grammaticality judgements over time. A goodness of fit test on the distribution of the Immediate Learning difference scores revealed that the distribution met the normality assumption for parametric group comparisons. However, a goodness of fit test on the distribution of the Delayed Learning difference scores indicated significant departure from normality (Shapiro-Wilk $W = .947$, $p = .0218$). Therefore, the Delayed Learning

difference scores were transposed to non-negative values by adding a constant of 10 difference points to all participants' scores, and then a log transformation was applied to normalize the distribution prior to performing group comparisons.

Group differences were analyzed using independent directional t-tests to determine whether the *ASL+English* group displayed significantly greater learning than the *ASL+Pictures* group. Because the distribution of initial ASL levels at the beginning of the experiment differed significantly between groups (Table 1), the t-tests were statistically adjusted to equate ASL level.

The *ASL+English* group had significantly higher improvement scores for immediate learning (adjusted mean difference = 1.67, SE = 1.03) than the *ASL+Pictures* group (adjusted mean difference = -.50, SE = 1.21), adjusted $t(48) = 2.10$, $p = .0207$, 1-tail. The *ASL+English* group had significantly higher improvement scores for delayed learning (adjusted log mean difference = 2.41, SE = .08 than the *ASL+Pictures* group (adjusted log mean difference = 2.24, SE = .10), adjusted $t(48) = 1.95$, $p = .0285$, 1-tail.

Figure 1 displays the improvement in immediate and delayed learning for the *ASL+English* group compared to the *ASL+Pictures* group as a percentage of their pre-learning baseline performance, after adjusting for group differences in ASL skill at the beginning of the experiment. That is, these results represent the percent improvement over pre-learning levels within each group, assuming that both groups had started their course work at the same level of ASL skill.

Their responses show that the participants prefer when there is some written English support in the classroom, and that they feel they learn better this way.

Figure 1. Comparison of two Teaching Methods (* $p < .05$).

Figure 2. Displays the participants' responses to the survey question, "I learn better when the teacher uses both ASL and written English during instruction."

CONCLUSION

The results of this study indicate that using written English in the ASL classroom to explain grammatical structures improves L2 college students' ability to judge whether conditional sentences are correct or incorrect. The findings are consistent with students' responses to a self-report survey question, where students reported that they prefer when their instructor uses some English (L1) in the ASL classroom to support their learning. These results support previous literature that suggest judicious use of L1 in L2 classrooms will help L2 students learn better (Cook, 2001).

We recognize that this study focusing on English as a learning tool may cause discomfort among some Deaf ASL teachers who are not comfortable using English in the ASL classroom. We understand that using English in the ASL classroom is a sensitive and controversial topic, and we want to emphasize that this study only examined using written English as a learning tool to help students understand ASL concepts where they might otherwise struggle. Using spoken English or Signed Exact English in the classroom is not being promoted here. Nor do these results imply that Deaf ASL teachers must be fluent in English to teach ASL. The results of this study simply suggest judicious use of English can support L2 acquisition of ASL.

There are limitations to this study that must also be addressed. Although the results suggest use of L1 may help L2 students learn ASL better, this study did not examine participants' ASL production. The study only examined participants' ability to judge whether conditional sentences were grammatically correct or not. Future studies should examine other

grammatical structures. Additionally, future studies should investigate the influence of teaching methods on students' ASL production, ideally through a longitudinal study which would research the effect of teaching methods on L2 communicative and linguistic competence.

Regardless of the ongoing debate in SLA about preferred teaching methods, scholars recognize that one dominant teaching method cannot be applied to a wide range of learners (Brown, 2014). Instead, teachers are encouraged to use an eclectic approach, where they employ a variety of methods and adapt their teaching methods to optimize students' learning experiences. In other words, the idea of a one-size-fits-all teaching method is not practical, and teachers and scholars should reconsider the role of the L1 in the L2 classroom.

ACKNOWLEDGMENTS

Special thanks to Dr. Matt Dye, Dr. Kim Kurz, Dr. Vincent Samar, Dr. Joseph Bochner, and Dr. Campbell McDermid for their supports. I also want to recognize my research assistants Eric Epstein, Megan Larson, and Eva-Alaine Thibault for their help with collecting data and literature for this study.

ABSTRACT

Language represents an intriguing and challenging topic, having fascinated mankind since its dawn. In the current study, our aim is to show the shortcomings of classical single-factor/unilateral theories of word learning, lexical acquisition, and language development, that generally tend to restrict these processes to single causes, constraints, factors or principles. Such theories imply a unilateral, linear growth pathway of language learning, acquisition, and development. Participants were 128 Moroccan children, 71 boys and 57 girls, aged between 4 and 12 years, all belonging to the social middle class. They lived in Taza city, capital of Taza province, a city in northern Morocco, 120 kilometers east of Fez, with a population of approximately 300,000 citizens, and surrounded by the Rif and Middle Atlas mountains. They were exposed to the two tasks, namely to the task of distinguishing between the appearance and the reality of a word and to the "False Belief Task on Word-Concept". We borrowed both tasks from the theory of mind and tried to adapt them to the field of linguistics, aiming at discovering the child's ability to distinguish between the *signifier* as an acoustic-linguistic reality, the *signified* as a mental entity and the *reference* as a physical/material entity. Findings of the current study support the pluralistic mentalist word theory.

Keywords: language acquisition and development; mentalist word theory, meta-cognition, meta-language, meta-representation, meta-semantics, meta-theory of mind, pluralistic coalition model, theory of theories.

1. THE DIFFERENT CONCEPTUAL FRAMEWORKS CONCERNING LANGUAGE/META-LANGUAGE ACQUISITION AND DEVELOPMENT AND THE MAIN GOALS OF THE PRESENT STUDY

Language represents an intriguing and challenging topic, having fascinated mankind since its dawn. In order to dissect this mystery, the Egyptian pharaoh Psamtik I, the Holy Roman Emperor Frederick II and the King James IV of Scotland carried out a “forbidden experiment,” namely the so-called “language deprivation experiment”, in which they isolated a sample of children and raised them with no human interaction, in order to verify to which language the first words would belong.

In the current study, our aim is to show the shortcomings and drawbacks of classical single-factor or unilateral theories of word learning, lexical acquisition, and language development, that generally tend to restrict these processes to single causes, perceptual/cognitive constraints (namely, reference, mutual exclusivity, shape, “whole object assumption” and “taxonomic assumption”), social factors or principles (such as innate forces, parent-child interaction, cultural scaffolding, self-construction, relevance, salience or the “dumb attentional mechanism”, among others).

Such theories, like the cognitive heuristic, the social-pragmatic or the associationistic conceptual frameworks, imply a unilateral, linear growth pathway of word learning, lexical acquisition, and language development, which is the same for all children worldwide.

For example, according to associationism, as stated by Paul Bloom (2006), “if two thoughts occur at the same time, they become associated, and one gives rise to the other. Children learn the meaning of rabbit, then, because the word is used when they are observing or thinking about rabbits. As a result, the words and the thoughts become associated, and children could be said to have learned what the word means”. Ellen Markman, while working on 4-years-old children, showed that taxonomic constraint could be a major driver in language acquisition and development (Carey & Markman, 1999).

However, these theories fail to explain language acquisition and development in “real-world” contexts and situations.

In order to overcome these limitations, we have adopted a different approach, namely the pluralistic paradigm called the “emergentist coalition model” (ECM; Hollich, Hirsh-Pasek & Golinkoff, 2000; Hirsh-Pasek, Golinkoff, Hennon & Maguire, 2004). According to this theory, multiple, differentially weighted factors, interacting in complex, non-linear ways, may contribute to word learning, lexical acquisition, and language development, as well as to the formation of the mentalist word theory. In particular, this approach is characterized, both in its formation and its functioning, by various types of variability, observable at different levels (namely, inter-individual, intra-individual, inter-contextual and cross-cultural).

Hence, the mentalist word theory is not governed by a linear pathway and a straight trajectory, but is represented by a highly dynamic and complex process. Thanks to multiple, co-occurring cues, children would, first, acquire word learning principles, which are supposed

to guide the following processes of lexical acquisition, vocabulary building and language development. These different steps also reflect specific developmental phases: for example, during infancy, attentional mechanisms could drive the process of mapping labels to “non-boring” objects, whilst, subsequently, in 10-month-old children the principle of “conceptual saliency” could prevail, and in 18-month-old children social cues, such as eye gaze and object handling, could guide the cognitive processes (Hollich, Hirsh-Pasek & Golinkoff, 2000; Hirsh-Pasek, Golinkoff, Hennon & Maguire, 2004).

In particular, our research questions were:

- 1) To which extent is the growth of the mentalist word theory in accordance with the principles of the pluralistic paradigm and, more specifically, in line with the multi-variability principle?
- 2) Which are the factors that may contribute to the acquisition, formation, development and refinement of the mentalist word theory?

2. WHAT IS A MENTALIST WORD THEORY

The concept of a mentalist word theory emerges from various modern psycho-cognitive approaches which underline that the young child, even before attending the school, is capable of building naïve (folk) theories about his/her own self and the world surrounding him/her. These theories enable him/her to understand and explain various phenomena, including complex ones. In other words, the child sometimes behaves like a novice scientist, reflecting upon himself/herself and the rest of the world.

He/she builds such theories on specific mental domains which deal with different phenomena occurring within his/her environment (Melot, 1997). Thus, he/she constructs naïve theories in physics (Spelke, Vishton & Hofsten, 1995), in biology (Gutheil, Vera & Keil, 1998) and also in psychology (Flavell, 2001).

Here in the current study, however, we will attempt to uncover another type of naïve theories: the child’s naïve linguistic theory. It is worth noting here that our understanding of the naïve linguistic theory has nothing to do with the Chomsky’s concept. Rather, it is based on various concepts within the theory of theories or the meta-theory or the theory of mind. Our definition of the above-mentioned concept is then dependent on the answer to this central question:

To what extent is the child at a certain age able to distance himself/herself in a conscious and neutral manner from language as a topic for reflection far away from day uses, or, in other words, to what extent is the child able to behave the way the linguistic researcher does?

Since language is a vast domain, we will limit ourselves to a relatively small component of it: namely, the word. We will attempt to investigate how the child formulates his/her mentalist word theory.

First point: what do we mean by a mentalist word theory?

We could explain this concept, starting from the definition of meta-semantics. When we talk about meta-semantic related activities, we refer to a person’s awareness and consciousness of the arbitrary relationship between a word and its reference. In other words,

meta-semantics is the part of a meta-language that deals with semantics. Some scholars define meta-semantics as the philosophy or the metaphysics of semantics.

To be more specific, referring to the three definitions of meta-semantics given by the researchers Alexis Burgess and Brett Sherman (2014), for meta-semantics we do not mean the basic meta-semantics (which aims to describe the grounds or metaphysical bases of semantic facts) or the metaphysics of semantic values (which deals with issues such as how semantic values should be thought of), but rather the theory of meaning (which explains or tries to explain the nature or essence of the semantics). As such, meta-semantics, dealing with analyzing and relating different concepts, aims to build a conceptual space within which semantic theories can be thought, formulated and developed.

The mentalist word theory, as we mean it, is a concept larger than the mere meta-semantic related dimension/activity. Indeed, a person's mental activity in forming and developing his/her mentalist word theory is not limited to self-representation and self-awareness of the kinds of the arbitrary relationship between a word and its reference, but includes also his/her ability to make representations of his/her own representations, comparing these representations with those expected to be formulated by other people. In other words, for mentalist word theory, we mean that ability to create meta-representations of one's own representations, in order to check one's own and others' understanding of the arbitrary relationship between a word and its reference. In more precise words, the mentalist word theory includes the skill to check to what extent oneself is capable of judging his/her own and others' beliefs about the word.

In order to discover the child's mentalist word theory, we used these two tasks:

The first is the task of distinguishing between the appearance and the reality of a word, and the second is the task of evaluating the child's capacity and ability to detect false beliefs about the word-concept.

We borrowed both tasks from the theory of mind and tried to adapt them to the field of linguistics, aiming at discovering the child's ability to distinguish between the *signifier* as an acoustic-linguistic reality, the *signified* as a mental entity and the *reference* as a physical/material entity.

The first task, then, aimed at measuring the extent to which a child is capable of distinguishing the word as a linguistic reality from the non-word as a mere linguistic phenomenon which does not refer to any linguistic reality.

The second task aimed at looking closely at the child's ability to understand others' perception of the relationship between a word and its reference.

3. THEORETICAL REFERENCES AND METHODOLOGICAL COMPONENTS

3.1. Theoretical References

Viewing the mentalist word theory from a coalition-pluralistic angle/ECM perspective requires us to first introduce the main characteristics and principles of the pluralistic paradigm, and second to briefly review the extant literature related to the pluralistic-coalition

approach advocated by the theory of theories in general and the mentalist word-theory in particular.

3.1.1. The Characteristics, Principles, and Stakes of the Pluralistic Paradigm

The main challenge for the pluralistic paradigm of the ECM is to overcome the shortcomings that plague and limit single-factor theories and unilateral models in explaining the growth and functioning of knowledge.

In the current study, when we speak of unilateral conceptual frameworks, we specifically refer to Jean Piaget's developmental stage theory, as well as to the Neo-Pagetian theories further developed and refined by his disciples (namely, Juan Pascual-Leone, Robbie Case, Graeme S. Halford, Kurt W. Fischer and Michael Commons, among others). It is well known that these unilateral approaches have dealt with the self from an epistemological viewpoint. In their conceptual frameworks, this self is characterized by stereotypes both in its growth and functioning that take the form of general rules (whole structures, hierarchical integration, and growth subordination, among others), which evolve in a linear, steady and increasingly growing pathway pertaining all cognitive domains and for all children worldwide, with no subject- and culture-related differences and nuances.

On the contrary, proponents of the pluralistic paradigm have stressed that the self is a psychologically complex, multi-faceted and variable concept; whose growth and development are characterized by various degrees and types of variability (as already mentioned, inter-individual, intra-individual, inter-contextual and cross-cultural variability) (Troade & Martinot, 2001).

The knowledge-building mechanisms of this self are also varied in that they are not limited to coordination or integration as Piaget believed, rather they extend to incorporate also impoverishing processes that continually disqualify a competence for a better one.

Hence, we can divide the knowledge-building mechanisms into two groups: the group of disqualification mechanisms and the group of enrichment mechanisms, as proposed by Mounoud (1990).

The set of impoverishing mechanisms deals with inhibiting one skill and keeping another active and well functioning (Houde, 1999; Houdé & Guichart, 2001). Other important differential mechanisms are given by the operations of interaction and of vicariance between processes; that is to say the skill of substituting and replacing one process with another fulfilling the same function, according to a given context or situation (Reuchlin, 1978; De Ribaupierre, 2005).

These principles stem from the more general principle of "cognitive redundancy". We can, also, include in this category of processes the operation of modularization which enables to distinguish a cognitive structure from another by making it more refined and specialized (Karmiloff-Smith, 1998; Fisher & Yan, 2002).

Whereas the group of enrichment mechanisms includes: i) the operation of bridging between different cognition domains (Demetriou & Kazi, 2001), or between various skills (Granott, Fischer & Parziale, 2002), ii) the processes of coalition that seek to create a conceptual change by integrating two different cognitive domains until they take the form of a new domain (Carey, 1985), and iii) the processes of representational re-description (Karmiloff-Smith, 1992) which aim at optimising a communication between all cognitive domains, by transforming implicit knowledge of each domain into an explicitly coded, formal knowledge.

These mechanisms can guarantee some kind of synergy and interaction between the cognitive processes of our knowledge system (Lautrey, 2003). Moreover, in an advanced level of growth, this dynamic synergy between processes may contribute to the foundation of a conscious knowledge that can take the form of a meta-concept (Carey, 1991) or of a hyper-cognitive domain, together with self-awareness and self-regulation (Demetriou, 1998).

Since the pluralistic conception within the ECM stresses that the growth of cognitive mind is based on varied patterns of unevenness, varied mechanisms of functioning and flexibility of its cognitive systems, it will not restrict itself to a linear, progressive and steady pathway only, but would rather be as varied as the variegation of cognitive domains and the diversification of forms of variability affecting the cognitive mind.

Hence, the growth of knowledge will oscillate between recession and regression in one area and progression and stability in another. Thus, the multiple pathways of growth are like a spider's web or a network (Fischer, Yan & Stewart, 2002).

3.1.2. The Pluralistic Approach of the Theory of Theories

Many modern researchers have tried to approach the theory of theories with a pluralistic view that is characterized by the principles that we have briefly explained in the previous paragraphs.

To be concise, these authors took a fairly critical stand towards a number of unilateral Piagetian concepts, such as the principles of whole structures and hierarchical growth (Fischer & Immordino-Yang, 2002). Moreover, they also refused to consider the small child, in the early years of his/her life, as an empty vessel or as a mere sensory-motor being, but rather they viewed him/her as a pluralistic subject capable of producing advanced, symbolic knowledge. They also abandoned the idea of dividing growth into stages of unilateral knowledge and, instead, asserted that this growth is characterized by different levels of varied domains of knowledge (Karmiloff-Smith, 1997; Mounoud, 2000).

They also challenged the Fodor's principle of modularity of mind and modular system of knowledge since this conceptual framework claims that knowledge functions according to a hierarchical, inevitable and stereotypical way (bottom-up), and that its modules are self-contained, independent and non-interactive.

Instead, they proposed a conceptual framework relying on dynamic systems whose style of treating knowledge varies according to the factors affecting it. Furthermore, they stressed that mental domains are not separate from each other but rather participate all together in an interactive way according to coalition relationships that end up formulating new specific domains. This would enable the mind to attain high levels of cognitive flexibility that sometimes take the form of meta-cognition (Karmiloff-Smith 1997; Carey 1985; Spelke, 2003; Vosniadou, 2007).

Moreover, they called for reconciliation between the constructional, the innate, and the social theories by stressing that mental knowledge is not wholly innate but rather pseudo-innate, and, as such, while growing, it has to maintain an interactive relationship with the dynamic system of knowledge, on one hand, and the environment, on the other hand, so that it will develop and grow into mature knowledge.

According to this view, mental domains should not be considered as specialized from the very beginning but rather pseudo-specialized (relevant domains). It is only thanks to the continuing operation of distinguishing and modularizing that it comes to draw and re-draw their epistemological frontiers. This would occur according to the nature of interactions

between the dynamic system of knowledge, its innate constraints and the new inputs it gets from the surrounding environment (Karmiloff-Smith 1994; Carey & Spelke, 1994).

3.1.3. The Mentalist Word Theory and the Pluralistic Coalition Conception

We would like to notice that the nature of the theses that we discussed earlier are those in line with the main topic of this study. This is in the sense that they view the mentalist theory from two main perspectives:

The first perspective is pluralistic in the sense that the authors and researches that promote this conceptual framework admit that language, as the mentalist word theory or the acquisition of other processes, is subject to various kinds of variance such as: intra-individual variability (Bassono, 1998), inter-individual variability (Karmiloff-Smith, 1997), inter-contextual variability (Karmiloff-Smith, Grant, Sims, Jones & Cuckle, 1996) and inter-linguistic/intercultural variability (Gopnik & Choi, 1995).

Furthermore, the development of the mentalist word theory is not restricted to progressive and accumulative pathways only but is rather subject also to unsteadiness, collapse and mutation (Bassono, 1999). It, therefore, takes the form of an unpredictable scallop-like trajectory.

The second perspective is coalitional in the sense that the scholars stress that multiple factors intervene in the formulation of the child's mentalist word theory. One such factor is the innate factor in the form of specific principles that guide the child's acquisition of the word-concept and his/her development of a theory hereupon (Hollich et al., 2000).

The socio-cognitive theory claims that language acquisition and development is driven by socio-cognitive factors, that can be demonstrated in the fruitful cooperation between the adult and the child learning a language (Carpenter, Nagell & Tomasello, 1998). Constructive factors include two distinct dynamics.

The first dynamics is characterized by complex, subtle modularising/specializing/discriminating processes and events whose role and activities result into the transformation of the domain of language from a vague domain (relevant domain) into a domain with well-defined concepts and with distinct epistemological characteristics (Carey, 1991).

The second dynamics is cooperative, meaning that the domain of language is not isolated from other cognitive domains but is rather open, interacting and cooperating with them, and this occurs through importing many cognitive processes that are of considerable help in its construction (Spelke, 2003).

3.2. Methodological Components

3.2.1. Hypotheses

The main working hypotheses that we formulated were:

- 1) The development of the mentalist word theory is mainly governed by the multi-variability principle.
- 2) Various and different factors intervene in the acquisition and subsequent development of the mentalist word theory.

3.2.2. Participants

Participants were 128 Moroccan children, 71 boys and 57 girls, aged between 4 and 12 years, all belonging to the social middle class. They lived in Taza city (in Arabic language: تازة), capital of Taza province, a city in northern Morocco, 120 kilometers east of Fez, with a population of approximately 300,000 citizens, and surrounded by the Rif and Middle Atlas mountains.

We randomly chose the population from two schools (namely, the “Petit Prince” kindergarten and school, and the “Fatima Al Fehria” school for elementary education). We concentrated specifically on children whose ages were in line with the legal ages set forth for education levels. Hence, the variable of education and age were integrated in one single variable, that is to say the schooling/age variable. Thus, we used the same symbol to refer to both variables (Table 1).

3.2.3. Experiment

This experiment was made up of two tasks that were in their turns divided into several items.

Table 1. Distribution of the population according to schooling/age variable

Education levels	2 nd Year	3 rd Year	1 st Year	2 nd Year	3 rd Year	4 th Year	5 th Year	6 th year
	Kindergarten		Primary school					
Mean age	4.2 years	5.3 years	6.3 years	7.4 years	8.4 years	9.5 years	10.5 years	11.5 years
Total	16	16	16	16	16	16	16	16
Symbols referring to schooling /age grades	A	B	C	D	E	F	G	H

3.2.3.1. The Task of Distinguishing the Linguistic Appearance from the Linguistic Reality of a Word

The aim of this task was to assess the subject’s ability to differentiate between the word as a linguistic reality (that in addition to its phonetic structure has a semantic meaning and a reference in reality) from the non-word (which has no sense and no reference because it is not a real word in any language).

Task, Items and Procedures

Before administering the different tasks, we explained the main objectives of our investigation to the recruited subjects. We specified that we wanted them to distinguish between the word as a linguistic reality because it has a meaning and refers to an object in reality, and the non-word which, even though for its linguistic structure, could appear to be a word, is not a real, existing word, because it has no meaning and does not refer to any subject in reality.

We, then, presented the subjects with two words (namely, “/madrasa/” or “school”, an existing word in Arabic language and “dattaà” as a non-word) as two examples of what we meant with the concept of existing word and the concept of non-word.

Afterwards, we presented them with the following instructions: i) to say whether these utterances are words or just random clusters of sounds that appear to be like words but are not; and ii) to justify their given answer.

These instructions applied to the following four utterances:

First item: first utterance “/kalima/” (meaning “word” in Arabic language)

Correct answer: 1. Incorrect answer: 0.

Second item: second utterance “/sabsabsab/” (a non-word)

Correct answer: 1. Incorrect answer: 0.

Third item: third utterance “/rajol/” (meaning “man” in Arabic language).

Correct answer: 1. Incorrect answers: 0.

Fourth item: fourth utterance “/bibibibiq/” (a non-word).

Correct answer: 1. Incorrect answer: 0.

Overall scoring: the sum of the expected ideal and theoretical answers: 4/4.

3.2.3.2. The False Belief Task on the Word-Concept

The aim of this test which is made up of five items was to measure the subjects’ ability to evaluate the beliefs of others regarding the concept of the word, in other words, this test aimed at verifying the child’s ability in hypothesizing the others’ ability to distinguish between the word as a mental linguistic reality and its reference as a material, physical reality.

The items of the task take the form of scenarios characterized by a narrative nature with characters such as the teacher, the mother, the father and peers, and Alice in Wonderland. The aim was to create natural, engaging and motivating contexts so that the subject would easily interact with the task on one hand, and positioning himself/herself in indirect situations so as to discover his/her opinion of the others’ belief regarding the word-concept.

In this regard, we agree with Karmillof-Smith et al. (1996) in stressing that indirect procedures which rely on games or narration are more effective than direct procedures such as explicitly asking “What does this word mean?” or giving instructions like “Divide this sentence into words”.

Task Items, Instructions and Procedures

Item (1): the subject was presented with the following scenario and was asked to evaluate it. “I asked Ali, a child with your age: “What is the biggest word in this sentence: “/dahabtu maàa alasdiqae àala matni aIqitar¹/” (meaning “I went with friends by train”, in Arabic language)? Ali answered that the biggest word was “the train”. I asked him why and he said that the biggest word was the train “because the train is the longest means of transportation. I asked Lamia, a girl one year younger than you, the same question and she

¹ We use the symbols of the International Phonetic Association (IPA) in order to transcribe Arabic utterances.

said that “the train” was not the biggest word in the sentence but the correct answer was rather “friends” “because it is made up of a larger number of words than the other words in the sentence [“words” instead of “letters”]”. Who do you think is right? And why?”

Scoring: appropriate answer 2, incomplete answer 1, inappropriate answer 0.

Item (2): the subject was presented with the following scenario and was asked to evaluate it. “We asked your father this question: “What is the smallest word in this sentence: “/adoda qorba zzahra/” (meaning “The worm is near the rose”, in Arabic language)?” and he answered “the worm” “because it is a very small insect”. We also asked Mustafa, a student, the same question and he answered “/qorba/” (meaning “near”, in Arabic language) “because it has the smallest number of letters than the rest of the words in the sentence”. Who do you think is right? And why?”

Scoring: the same as previous item 1, that is to say appropriate answer 2, incomplete answer 1, inappropriate answer 0.

Item (3): the subject was presented with this scenario and was asked to evaluate it. “I asked your teacher to draw the word “ghost” (“/chabah/”, in Arabic language) and she gave me this (I presented him/her with a ghost picture). Then I asked your mother to draw the word “ghost”, but she answered that it is not possible to draw the word “ghost” “because the word can be read, written and uttered, but we can only draw a picture of a ghost, not a picture of the word “ghost”. As such, the task is not feasible”. In your view, was the teacher right? Or was your mother right? Can we draw the word “ghost”? How? Why?”

Scoring: the same as previous item 1, that is to say appropriate answer 2, incomplete answer 1, inappropriate answer 0.

Item (4): the subject was presented with the following scenario and was asked to evaluate it. “I asked your friend Osama to buy me a candy with the word “/dirham/” (which is a Moroccan currency, in Arabic language). He shouted at me and said that he could not buy a candy with the word “/dirham/”/ “because it is just a word”. Therefore, he asked me to give him a real “/dirham/” to buy a candy. Now, can you buy a candy with the word “/dirham/”? How? Why?”

Table 2. Symbols of the mentalist word theory-based experimental items

Tasks	Items	Symbols
The task of distinguishing between linguistic appearance and linguistic reality of a word	Item 1	Word
	Item 2	Sabs
	Item 3	Man
	Item 4	Bibib
	Overall scoring of items	OSI
False belief task on word concept	Item 1	Train
	Item 2	Worm
	Item 3	Ghost
	Item 4	Dirham
	Item 5	Alice
	Overall scoring of items	OSI

Scoring: the same as previous item 1, that is to say appropriate answer 2, incomplete answer 1, inappropriate answer 0.

Item (5): the subject was presented with the following scenario and was asked to evaluate it. “Alice travelled to Wonderland, a strange place, completely different from other places in the world; there, she found Humpty Dumpty who changed the dog’s name and called it “cat” and so the dog began to cry like a cat. He also changed the cat’s name and called it “dog” so it began to bark like a dog. All this happened in Wonderland. Do you think that this would be possible in our real world? Can we change animals’ cries and characteristics by changing their names? How? Why?”

Scoring: the same as previous item 1.

Overall scoring (OSI): The sum of the expected ideal theoretical answers ($2 \times 5 = 10$).

4. ANALYSIS, EXPLANATION AND DISCUSSION OF RESULTS

4.1. Analysis of Results

4.1.1. The Task of Discriminating Linguistic Reality from Linguistic Appearance

4.1.1.1. Effect of the Age/Schooling Factor on the Subjects’ Answers in the Task of Discriminating Linguistic Reality from Linguistic Appearance

Table 3. Means and percentages of correct answers in the task of discriminating linguistic reality from linguistic appearance, according to age/schooling variable

Schooling/ age	Word		Sabs		Man		Bibib		OSI	
	%	Mean	%	Mean	%	Mean	%	Mean	%	Mean
A	68	0.68	87	0.87	81	0.81	81	0.81	79	3.18
B	93	0.93	100	1	100	1	100	1	98	3.93
C	93	0.93	100	1	100	1	100	1	98	3.93
D	93	0.93	93	0.93	100	1	100	1	96	3.87
E	100	1	100	1	100	1	100	1	100	4
F	100	1	100	1	100	1	100	1	100	4
G	100	1	100	1	100	1	100	1	100	4
H	100	1	100	1	100	1	100	1	100	4
All	93	0.93	97	0.97	97	0.97	97	0.97	96	3.86

Analysis of variance (ANOVA) revealed that the means of OSI varied significantly with the age factor ($F_{(7,120)}=6.18$, $P < 0.001$). Table 3, however, showed that the lowest value for correct answers recorded for the four-year-old subjects exceeded 70% with a mean of 3.18, while the eight-year-old group got the highest value of correct answers (100%) with a mean of 4. The five-year-old and the six-year-old groups got 98% with a mean of 3.93. This value decreased to 96% with a mean of 3.87 when considering the seven-year-old group.

This showed that there was no a clear pattern of sustained increase that started with a lower level and moved on to a higher one, as we found that about 79% of the lowest age group were capable of distinguishing between the linguistic reality of a word and its linguistic appearance (resemblance). Further, since the age of six years, the subjects’ answers seemed to

satisfy enough the required value of correct answers which was achieved at the age of eight years.

Although the subjects' answers to the "word" item varied significantly according to the age factor ($F_{(7, 120)}=3.42$, $P < 0.01$), we should notice that its lowest percentage exceeded the percentage of 60% for the youngest age group, while the five-, six- and seven-year-old groups scored 93%, with a mean of 0.93. These values were close to 100% (with a mean of 1), which was achieved by the groups of eight-year-old and older children (as can be seen in Table 3).

The mean values of correct answers to the items "man" and "bibib" varied significantly with age ("man" item: $F_{(7, 120)}=3.46$, $P < 0.01$; "bibib" item: $F_{(7, 120)}=3.46$, $P < 0.01$).

This variance, however, did not take the form of a sustained increase as six-year-old and older children reached the ideal percentage of 100% with a mean of 1. Subjects belonging to the four-year-old group approximated this value as they scored 81% with a mean of 0.4 in both items (as can be seen in Table 3).

Concerning the "bibib" item, we should notice that answers were not affected by the age factor ($F_{(7, 120)}=1.54$, not statistically significant), and this means that the mean values of correct answers for different age groups were quite close to each other with regards to this item.

4.1.1.2. The Effect of the Horizontal Comparison Factor on the Subjects' Answers to the Task of Distinguishing between Linguistic Reality and Linguistic Resemblance

Performing our experiment, we were able to observe that the difference in all subjects' answers to the items of the task of distinguishing between linguistic resemblance and linguistic reality of a word, was not statistically significant ($F_{(3, 360)}=2.26$, not statistically significant).

Diagram 1. Percentages of correct answers given by all population in replying to the items of task of distinguishing between linguistic appearance and linguistic reality.

This proves that task items, regardless of their being varied, did not affect the performance of the subjects in a statistically significant way. In other words, the number of correct answers of all subjects to the different items was relatively the same, in that the lowest value scored for the "word" item 93% with a mean of 0.93, whereas other items scored the

same value (that is to say, 97%) and the same mean value of 0.97 (as can be seen in Table 3 and in Diagram 1).

4.1.1.3. The Level of Interaction between Age and Horizontal Comparison Factors in the Task of Distinguishing between Linguistic Appearance and Linguistic Reality of the Word

The interaction between the age factor and the horizontal comparison factor appeared to be not significant ($F_{(21,360)}=0.67$, not statistically significant). This in turn shows some relative similarities between the growth pathways of subjects' answers to different task items (as can be seen in Diagram 2).

Diagram 2. The growth pathways of subjects' answers to different items of distinguishing between linguistic appearance and linguistic reality.

4.1.2. False Belief Task on Word-Concept

4.1.2.1. Effect of the Age-Schooling Factor on the Subjects' Answers to False Belief Task on Word-Concept

ANOVA unveiled that the mean values of OSF varied significantly through age evolution ($F_{(7,120)}=35.250$, $P < 0.001$). The extreme values related to four-year-old and eleven-year-old groups, respectively, which ranged between the mean of 2 and 10 (Table 5).

Insufficient answers to the "train" item were restricted to the four-year-old subjects with a percentage of 25% and to the five-year-old group with a percentage of 6%. Correct answers, however, covered different age groups, and they were situated between the percentage of 100%, obtained by the eight-year-old and the eleven-year-old groups, and the percentage of 12% observed in the five-year-old group.

Table 4. Percentages of correct answers and insufficient answers to the false belief task on word-concept

Items	Train		Worm		Ghost		Dirham		Alice	
Schooling/ age groups	Correct answers	Insufficient answers	Correct answers	Insufficient answers	Correct answers	Insufficient answers	Correct answers	Insufficient answers	Correct answers	Insufficient answers
A	12	25	25	6	0	6	18	0	25	0
B	37	6	31	6	18	18	69	0	63	6
C	81	0	75	0	45	0	63	0	75	6
D	94	0	94	6	81	0	75	0	94	6
E	100	0	100	0	69	0	94	6	100	0
F	94	0	100	0	69	0	100	0	100	0
G	94	0	94	0	100	0	94	0	100	0
H	100	0	100	0	100	0	100	0	100	0

Table 5. Means of correct answers and insufficient answers to the false belief task on word-concept

Items	Train	Worm	Ghost	Dirham	Alice	OSF
Schooling/ age groups	Mean	Mean	Mean	Mean	Mean	Mean
A	0.5	0.5	0.06	0.37	0.5	2
B	0.81	0.68	0.93	1.37	1.31	5.12
C	1.62	1.5	0.87	1.25	1.62	6.81
D	1.87	1.93	1.62	1.5	1.93	8.81
E	2	2	1.37	1.937	2	9.31
F	1.87	2	1.87	2	2	9.75
G	1.87	1.87	2	1.875	2	9.62
H	2	2	2	2	2	10

Generally speaking, what is noticeable is that the means of the “train” item also changed with age evolution ($F_{(7,120)}=15.691$, $P < 0.001$), as it was subject to a gradual increase that reached the highest level with the eight-year-old group, while slightly decreasing with the nine- and ten-year old groups and getting back with 11-year-old subjects to the same high level obtained by the 8-year-old group.

If insufficient answers to the “worm” item were given only by the 4-, 5- and 6-year-old groups with a marginal percentage of 6%, correct answers, however, covered all age groups, and ranged between 25%, observed for 4-year-old subjects, and 100% observed for the 8-, 9-, 11-year-old groups. Therefore, the means of the “worm” item increased significantly with age evolution ($F_{(7,120)}=17.651$, $P < 0.001$), in a linear trajectory, attaining the highest value with 8- and 9-year-old subjects, slightly declining with 10-year-old subjects and getting back with 11-year-old subjects to the same high value obtained by the 8- and 9-year-old groups.

Further, other points that should be noticed are the following ones:

- Insufficient answers to the “ghost” item were observed with four-year-old subjects with a percentage of 6% and with the five-year-old group with a

percentage of 18%. Whereas, except for four-year-old subjects, all other age groups scored correct answers with a percentage between 18% obtained by the five-year-old group, and 100% for the ten- and eleven-year-old groups. What is noticeable is that the mean values of the “ghost” item increased with age growth ($F_{(7,120)}=15.673$, $P < 0.001$) as they were subject to some fluctuations with a light increase between the age of four and nine years, and reaching the highest value at age of ten and eleven years (as can be seen in Table 4).

- Unsatisfactory answers to the “*dirham*” item were restricted to eight-year-old groups only. Whereas, all other age groups scored correct answers with a percentage of 18%, recorded for the four-year-old subjects, and 100%, reached by both nine- and eleven-year-old groups (as can be seen in Table 4). We also noticed that the mean values of the “*dirham*” item increased with age ($F_{(7,120)}=10.753$, $P < 0.001$) in an unsteady manner (effect shown in Diagram 5).
- Unsatisfactory answers to the Alice item were given by five- and six-year-old subjects with a percentage of 6%; whereas correct answers were scored by different age groups, ranging between 25%, recorded for four-year-old subjects, and 100%, reached by 8-, 9-, 10- and 11-year-old and older children. Overall, the mean values for the Alice item gradually increased as children grew older ($F_{(7,120)}=15.229$, $P < 0.001$); this increase reached its peak at the age of eight years.

4.1.2.2. Effect of the Horizontal-Comparison Factor on the Subjects’ Answers to False Belief Task on Word-Concept

Means of answers (considering the sum of both correct answers and unsatisfactory answers) of all subjects to the false belief task on word-concept varied from one item to the other ($F_{(4,480)}=6.125$, sign with $P < 0.001$), ranging from a percentage of 21.7% for the Alice item, to a percentage of 20.4% for the “train” item, to a percentage of 20.3% for the “worm” item, to a percentage of 20.0% for the “*dirham*” item, whereas the “ghost” item scored the least percentage (17.5%) (Figure 3).

Diagram 3. Percentages of correct answers and insufficient answers given by all population in replying to the items of the false belief task on word-concept.

4.1.2.3. The Level of Interaction between Age Factor and Horizontal Comparison Factor in the False Belief Task on Word-Concept

The interaction between horizontal comparison and age was statistically significant ($F_{(28,360)}=1.836$, $P < 0.001$), which indicated that the growth pathways of the subject's answers to the items of the test of wrong belief were not uniform. However, we observed in Diagram 4 that they became uniform starting at the age of nine years, reaching a *plateau*.

Diagram 4. The growth pathways of subjects' answers to different items of false belief task on word-concept.

4.2. Explanation of Results

To explain the data in the experiment related to the mentalist word theory, we should answer the following questions:

- What is the nature of the growth pathways of the mentalist word theory?
- To what extent could these pathways be termed “plural” or “pluralistic”?
- To what extent is the principle of “multi-variability” or “poly-variability” present in the dynamics of the evolution of the mentalist word theory and its functioning?
- How multiple are the factors that contribute to the development of the mentalist word theory?

4.2.1. The Development of the Mentalist Word-Theory

4.2.1.1. The Development of the Competence of Distinguishing between Linguistic Appearance and Linguistic Reality of the Word

Data from the task of distinguishing between linguistic appearance and linguistic reality of a given word revealed that the percentage of successful subjects' answers surpassed a percentage of 70% at the age of four years, and got closer to 100% at the age of five years. The percentage of 100% was reached since eight years of age.

Hence, there is not a linear and sustained growth pathway that starts with cognitive weakness and moves on to reach cognitive expertise, in that even very young children have a fair amount of such expertise.

The question is why and how are even four year old subjects able to distinguish between the linguistic reality of a word and its linguistic appearance? Is it because of schooling? Or are there other factors playing a major role?

It is evident that these children are newcomers to kindergarten and, as such, we believe that schooling is not a sufficient reason to explain their success in the task of distinguishing between linguistic reality of a word and its linguistic appearance. This, undoubtedly, means that the child comes to kindergarten with already-established beliefs and naïve hypotheses, and these enable him/her to pass the linguistic task so successfully.

Scholars like Hollich et al. (2000) and Carey and Markman (1999) have wondered how the child could acquire and develop language in such a short period of time; we, also, cannot avoid asking the same question in relation to the experiments we conducted.

More specifically, we wonder how the kindergarten pupils were so successful in the task of distinguishing between linguistic reality of a word and its linguistic appearance.

The reality is that the child may be pre-equipped with certain principles and constraints that guide him/her to understand the word-concept; we believe that these same principles and constraints are used by our subjects while dealing with the linguistic task, and these conceptual principles are as follows:

Reference principle: this appears at the pre-linguistic stage and it is manifested in the child's tendency to look closely at the subjects/things we name (Hollich et al., 2000). It appears that, in our experiment, four-year-old subjects tended to exploit this principle when they refused to consider the items “sabsab” and “bibibiq” as words as they have no reference in the real world. We should notice that over-generalizing the use of this principle may result in the fact that some subjects refused to consider the word “word” as a word as it has no real reference. They, indeed, explained that word is “not a word because we don't understand it; because it is not a thing”.

The Extendibility principle: this principle means the child's understanding since two years of age that the name is not an attribute of a specific subject/thing alone, but that it can refer to various subjects/things (Hollich et al., 2000). This reflects the fact the child has started to become aware of the nature of the arbitrary relationship between a word and its reference. Hence, we believe that the subjects of our experiment, especially the very young ones, that were successful in the “word” item task, relied on this principle: in that they believed that, as the word-concept refers to no specific material subject, it should be perceived and understood as extended, and that the names of all subjects are words. Thus, their justification was as follows: “the word is a word because we understand it; bread is a word, milk is a word, the table is a word, too”.

Object scope or whole object assumption principle: at an early age, the child formulates the belief that every name refers to the whole object and not just to some of its parts, components and attributes, and that it does not refer to events and actions (Hollich et al., 2000). We consider quite probable that the kindergarten pupil utilized this principle while dealing with the “man” item task as we got the following justifications: “man” is a word “because we name him man, because it is the name of a human being, because we use it to name the teacher and dad, for example”.

Conventionality principle: This is the child's attempt of getting rid of words that he/she (or someone else) invented, while embracing words that the family and society have agreed upon (Hollich et al., 2000). Hence, the subjects relied on this principle when they refused to consider the words “*sabsab*” and “*bibiq*” as words because for them no social convention or norm exists for these words. Thus, they formulated the following justification: “*bibiq*” is not a word “because we don’t hear it so often, “*bibiq*” is not a word because we don’t understand it, it is just a nonsense.”

The Novel name-nameless category: this principle has been recently reformulated by Hollich et al. (2000), It is known also as principle of mutual exclusivity (Markman, & Wachtel, 1988). This refers to the young child’s tendency to attach every invented name to a new still-nameless subject/object. We think that the supremacy of this principle over the child’s mentalist word theory leads him/her to consider a number of non-words as real words that refer to specific references. This is what we were able to deduce from justifications as these: “*sabsabsab*” is a word “because we name dogs “*sabsabsab*”. “*Bibibiq*” is a word because we hear “*bibibiq*” in the street”.

As such, it becomes clear that there are a number of specialized principles that guide the child in differentiating between linguistic appearance and linguistic reality of the word. For the recruited subjects, these principles may have helped to draw the frontiers of the domain of language and to lay the foundations of what we call the naïve linguistic theory.

Therefore, we conclude that even if the linguistic domain contains specific linguistic principles, it is not isolated from other cognitive domains, but is rather in interaction and in addition to the previous ideas.

For example, Melot (1999) stated that the child between the age of 4 years and of 5 years could be capable of discriminating the appearance of a thing from its reality. Still, what attracts much attention, according to our data, is the fact that the child is able of distinguishing between linguistic appearance of the word and its linguistic reality at such an early age.

Hence, we can ask the following question: why do these children succeed in the two tasks simultaneously?

We believe that the child at this age begins to understand that the mind can produce various and different representations about the same object (Melot, 2001). Subsequent to this is the emergence of the skill of distinguishing between mental entities (that is to say, beliefs, representations) and their corresponding material entities.

In our view, this is a general skill, belonging to the domain of the theory of mind, and it influences the child’s mentalist word theory, thus helping him/her to distinguish between the linguistic appearance of the word (non-word) and its reality (real word).

4.2.1.2. The Development of the Skill of Evaluating the False Belief Task on Word-Concept

Age evolution does certainly influence the advancement of the skill of differentiating between miss-representation of the word-concept and its appropriate representation. Whereas, the development of correct answers to the items of false belief task about word-concept is not always linear.

We observed, indeed, a wide diversity of development trajectories, which follow varied multi-step, progressive, regressive or stable pathways. For instance, we found that correct answers to the “ghost” item were stable for 8-9-year-old groups (69%). Nevertheless, 8-9-

year-old subjects were less successful in correctly answering to the “ghost” item task than the 7-year-old group which attained a higher percentage (81%). Further, we can notice some slight regress in the answers to the “train” item for 9-10-year-old subjects (94%) and the 8-year-old group (100%). Also, this could be noticed in analyzing and discussing the answers to the “worm” item for 10-year-old subjects (94%) as well as for the 8-9 year-old group (100%). Furthermore, we observed the same trend in the answers to the “*dirham*” item task for 6-year-old-subjects (63%), as well as for the 8-9- and 5-year-old groups (69%).

Hence, the trajectory of the skill of evaluating the false belief task on word-concept oscillates between stability and regression in one area and progression in another one. This leads us to describe it as pluralistic pathway.

We would like to notice, however, that when we stress the diversity of the rhythm of growth pathways formation and development for the skill of evaluating false belief on word-concept, we do not mean to reject the hypothesis that the mentalist word theory may evolve through constructive dynamics.

While reviewing subjects’ answers, we noticed clear differences between justifications given by kindergarten children and advanced students, in that ambiguous justifications were restricted to kindergarten children with an average of 12.5% but were practically non-existent for other school levels; such justifications were fully irrelevant and contained no clear causal connectors.

For example, we considered an irrelevant justification to the “worm” item, a reply like “I choose the flower because we can give it to someone as a gift” or “The worm is the smallest word because it can fly”. We considered an irrelevant justification to the “ghost” item an answer like “We do not draw the word “ghost”, we write it because it can be written easily”, or “We don’t draw the word “ghost” because it cries”.

What is noticeable, however, is that the majority of justifications, though classified as incorrect answers, were based on clear causal explanations. For example, in the case of the “train” item task, “The word “friends” is longer than the word “train” because we have many friends”, “The word “train” is longer because the train is very long”, or in the case of the “worm” item task “The “worm” word is the smallest word in the sentence because the worm is so small that it can go inside peas”. In the case of replies to the “*dirham*” item task, “With the word “*dirham*”, we can buy cakes”, or in the case of the Alice in Wonderland task, “It is possible because it was a dog, but when we gave it milk and called it pussy-cat it began to mew, and if we called it dog, it would have started to bark”.

Such answers revealed the existence of a causal-explanatory linguistic theory that still lacks the dimension of the arbitrary relationship between the word and its reference, as it considers the word a material attribute/ a characteristic inherent to the subject/object it refers to. Thus, it can be termed as a naïve theory.

However, if we know that the child, in the early years of his/her schooling, is highly likely to encounter the arbitrary relationship between the word and objects and to familiarize with such concept, it becomes obligatory to wonder about which strategy he/she uses to deal with this idea. Does he/she give up once and forever to his/her naïve theory together with his/her deeply rooted naïve linguistic beliefs and replace them with a serious, scientific linguistic theory? Does he/she stick, instead, to his/her first naïve theory at the expense of a more scientific one?

We should notice that the justifications provided by pupils at higher kindergarten levels and at the first level of elementary education indicated that they very often tried to combine

their naïve representations together with their school-learned scientific knowledge, and this lead them to formulate a mixed or rather synthetic theory.

This is, indeed, what can be inferred from the following justifications given to the “ghost” item: “We don’t draw the word “ghost”, we write it instead, because it’s very big and it’s difficult to draw; we don’t draw the word “ghost” because it would appear to us while drawing it”. To some extent, the child has begun to become aware of the stenographic and abstracting function of the word; as in the given explanation, transforming the ghost from a material object to an abstract entity so that it would not appear: “It is too big to be a word”.

The following example (the justification given to the “*Dirham*” item task) goes in the same direction: “We can buy nothing with the word “*dirham*”, because it’s just a word, and the word is just like a piece of paper; can we buy anything with a piece of paper? Can we buy something with nothing?”

Such a justification shows that the child has started to become aware of the fact that the word is an abstract entity but still is unable to declare it. This is so, because he/she is still not capable of getting rid of naïve beliefs altogether. Later on, and as a result of the influence of the schooling factor, on one hand, and the cognitive-maturity factors on the other hand, the child is convinced of the necessity of giving up to his/her complex, hybrid linguistic theory for embracing a scientific one.

This is, in fact, what the following justifications given to the “train” item task shows: “The word “*/asdiqae/*” (meaning “friends” in Arabic language) is the longest word in the given sentence because it contains many letters”.

Also the explanation given to the “worm” item seem to suggest a similar process: “The word “*/qorba/*” (meaning “near” in Arabic language) is the smallest word in the sentence because it contains just three letters”.

The same trend can be observed in the explanation given to the “*Dirham*” item (“No, because it’s just a word and not a real *dirham*”), in the case of the reply to the “ghost” item task (“It is not possible, because drawing is not like writing”) or in the answer to the Alice in Wonderland task (“Because the dog’s barking does not change even if we would change its name, the name is just a name, it has no impact on animals”).

Hence, the schooling factor plays a fundamental role in the development of the child’s mentalist word theory (higher kindergarten level and first level at elementary school).

In addition, the following answers further reinforce this fact: in the case of the “train” item “The word “*/asdiqae/*” (meaning “friends” in Arabic language) is the longest word in the given sentence, because it contains many words [instead of letters]” or “The word “train” is very long to write”. These justifications/explanations will, at advanced levels, be replaced by the following ones: “The word “*/asdiqae/*” (meaning “friends” in Arabic language) is a long word because it contains six letters”. This means that it is schooling that enables the child to differentiate between the concept of the letter and the concept of the word.

Overall, it can be said that the development of the child’s mentalist word-theory, which is a co-product of the schooling factor and the dynamics of internal construction, is realized through a set of gradual conceptual changes that move from a naïve theory to a synthetic one and are finally crowned with the establishment and development of a serious, scientific theory (Vosniadou, Skopeliti, I. & Ikospentaki, 2004).

It should be noticed that this conceptual change of the child’s mentalist word theory is subject to variability from one item to another. For instance, even if more than 60% of five-year-old subjects are able to provide correct answers to the “*Dirham*” item and to the Alice in

Wonderland task, we do not get such a satisfactory percentage for the item “/doda/” (meaning “worm” in Arabic language) and “/qitar/” (meaning “train” in Arabic language) in subjects with less than six years of age.

Concerning the replies to the item “/chabah/” (meaning “ghost” in Arabic language), the above-mentioned percentage is reached at eight years of age.

Hence, items’ development pathways are varied even if they have the same objective, which is to measure the subjects’ ability of evaluating a number of representations on the relationship between a word and its reference. This ability varies depending on the level of difficulty and complexity of each item; some are highly complex such as the item “/chabah/” (meaning “ghost” in Arabic language); others are less complex, such as the word “Dirham” item and the Alice in Wonderland task.

As such, the development of the mentalist word theory is not context-independent but rather context-dependent. In simple and easy situations (distinguishing between linguistic appearance and linguistic reality of a word, the “Dirham” item and the Alice in Wonderland task), the child is able to express and convey very advanced, sophisticated representations on word-concept at an early age.

However, in tricky and challenging situations or ambiguous contexts, it is necessary for the subject to be older in order to express appropriate conception of the word, as was, for example, stated by researchers like Fischer & Yan (2002).

4.2.2. The Mentalist Word Theory and the Multi-Variability Principle

If the multi-variability or poly-variability principle constitutes the principle tenet of the pluralist paradigm, the question is to what extent does this principle affect the child’s construction of a mentalist word theory?

In the following paragraphs we will focus on the different kinds of variability in order to give a serious reply to this crucial question.

A. The Multi-Variability Principle and the Task of Distinguishing between Linguistic Reality and Linguistic Resemblance of a Word

A.1. Inter-Individual Variability

In our experiments, we found that inter-individual differences were almost non-existent in the task of distinguishing between linguistic appearance and the linguistic reality of the word, since the majority of subjects reached the required maximum in answering this task, with the exception of four-year-old subjects.

As such, overall, there was a marginal presence of this kind of variability: namely, for the “word” item 68% were successful *versus* 32% unsuccessful, for the “Sabs” item, 87% successful *versus* 13% unsuccessful, for the “man” item 81% successful *versus* 19% unsuccessful; for the OSI 79% successful *versus* 21% unsuccessful.

A.2. Inter-Contextual Variability

Since horizontal comparison was found to have no impact on the subject’s answers to the test of discriminating linguistic appearance from linguistic reality, this reveals outstanding

similarities in their performances with regards to other task items. This leads to the eventual removal of inter-contextual variability.

A.3. Intra-Individual Variability

The reasoning formulated for the inter-contextual variability applies also the intra-individual variability.

A.4. Cross-Cultural Variability

We would first mention that it is really hard to draw any kind of cultural comparison between the present study and other Western studies since the nature of the items and the instructions used in our experiment have not been adopted in any of the previous researches. Therefore, this puts aside any kind of uniformity on the level of the experiment condition.

However, Baker's (1984) experiments resulted in the same conclusion that children between the ages of five and seven years do distinguish the word from the non-word.

Flavell, Speer, Green, August, (1981) concluded that four- and five-year-old children express their non-understanding of rare words. Such findings do further reinforce our hypothesis that the competence of distinguishing between linguistic reality and linguistic appearance is indeed a pre-school activity. We recorded that about 79% of four-year-old subjects performed well in the task of discriminating linguistic reality from linguistic appearance.

However, a study carried out by Bowey, Tunmer and Pratt (1984) demonstrated that the child can only discriminate the word from the sound after six years of age.

In the same context, Downing, (1969, 1970, 1972) performed several experiments in which five-year-old groups were presented with a number of sounds (natural, sounds, noise, phonemes, words and sentences) and were asked to say "yes" when they recognized a word in this chain of sounds. The outcome was that none of the subjects was successful in the task.

We believe that the main reason behind such differences and discrepancies between these findings and our result, is not related to the cultural variable but is rather mainly because of the nature of the tasks: their difficulty level and their degree of appropriateness to the child's mentality.

B. Multi-Variability Principle and the False Belief Task on Word-Concept

B.1. Inter-Individual Variability

Inter-individual differences in seven-year-old children and older groups remain marginal. Indeed, most subjects from the age of seven years on reach the maximum required value of correct answers in the task of the false belief on word-concept. There is, however, a significant inter-individual variability in all age groups younger than seven years.

B.2. Inter-Contextual Variability

The performance of the majority of subjects varies slightly from one item to another. For most items, correct answers fluctuate between 20% and 21%. We should notice, however, that the "ghost" item is a significant exception to this as subjects scored the lowest percentage (17%).

We believe this is so because the item is an inappropriate situation to the child and the reference is an abstract and imaginary entity (the ghost). Within the same context, De Villiers (1978) concluded that the child refuses to consider the “ghost” as a word because the ghost does not exist.

B.3. Intra-Individual Variability

More than 70% of the recruited subjects were successful in the task of discriminating linguistic appearance from linguistic reality since four years of age. However, we have to wait until six years of age to get acceptable percentages in the false belief task on word-concept. This means that most subjects were more successful in the first task than in the second task.

In other words, we can depict this kind of cognitive behavioural change for the same individuals from one situation to another as a sort of intra-individual variability.

B.4. Cross-Cultural Variability

Berthoud-Papandropoulou and Sinclair (1974)’s study is somewhat similar to our study especially concerning tasks and procedures. This study found out that the six-year-old child is incapable of comprehending the arbitrary relationship between a word and its reference, and only starts becoming aware of this relationship at the age of seven years. Before this age, when asked to give examples of long words he/she gives words that refer to long things (reference). He/she also considers the words “cigarette”, “box” and “worm” as short words because they refer to small subjects/objects. Although the seven-year-old child starts becoming aware of the independence of the word from its concept, he/she continues to refusing to consider conjunctions, pronouns and adverbial particles as words, because for him/her they do not refer to real references (that is to say, real subjects or real things) (Berthoud-Papandropoulou 1978, 1980).

Another study of Osherson and Markman (1975) concluded that five-year-old subjects refuse to substitute the word “sun” for the word “moon” because they believe the sky would not get any darker; these children also believe that changing the dog’s name and calling it “cat” makes it mew.

On the contrary, our study concludes that more than 70% of the six-year-old group were aware of the arbitrary relationship between the word and its reference; and more than 70% of these refused to consider the word “worm” as the smallest word in the sentence and tended to replace it with the word “near” (*/qorba*² in Arabic language), because it contained the least number of letters, regardless of the difficulties that this word could pose in that it does not refer to a concrete subject or thing but is rather a spatial adverbial particle.

Also, our data reveals that approximately 80% of subjects at 6 years of age could recognize that the biggest word in the sentence was not the word “train” but the word “friends”. As such, we are in accord with Bialystok (1986)’s experience when the researcher asked children between 5 and 6 years of age to determine the smallest and biggest word in a given list of words (“hippopotamus”, “train”, ...). The outcome was 67% of correct answers at 6 years of age *versus* 28% of correct answers given at 5 years of age.

² When we consulted an Arabic grammar book (“*jamia doros al arabiya*”, in Arabic language) on this point we found the following: the word “near” (in Arabic language, “*/qorba*”) is not considered as a spatial adverbial particle, meaning that in Arabic language it has no concrete representation that can be perceived.

In addition to what already said and discussed, more than 60% of five-year-old subjects in our study accepted the possibility of substituting the cat's name with dog with no impact whatsoever as to the animal's physical characteristics.

We should notice that the discrepancy between our data and the previously cited data is not only due to cultural differences but can rather be explained by the nature of the procedures used and opted for optimal contexts.

As a matter of fact, the items of the false belief task on word-concept were made up of dialogs with different characters (namely, the father, the mother, the teacher, Alice in Wonderland, Humpty-Dumpty, and pupils) and these added a playful, engaging dimension, making it easier for the child to better-express his/her meta-semantic activities at an early age.

However, the previously cited studies mostly used direct questions, like "What does this word mean to you?" and sometimes tricky, challenging or too sophisticated situations that exerted some sort of inhibition on the subject and did not allow him/her to express his/her mentalist word theory skills.

4.3. Discussion of Results

In discussing the results of this experiment, we will focus on the following points:

4.3.1. *The Pluralistic Characteristic of the Mentalist Word Theory*

According to Piaget (1926), the child becomes aware of the arbitrary relationship between the word and its reference through a linear, progressive and sustained growth pathway. Until six years of age the child considers the word as being an intrinsic attribute of the subjects/objects it refers to (the "sun" is called "sun" because we can see it or because it is hot); between seven and eight years of age the child believes that God or a God-like creature creates things with their names, at nine years of age he/she starts to consider the word as a result of social convention, and only deals with it as a symbol when he/she reaches ten years of age.

The growth of semantic awareness for Piaget depends on the general cognitive growth. Indeed, he claimed that the various cognitive domains (namely, serial arrangement, conservation, inclusion, and semantic awareness) are, on one hand, subject to the principle of whole structures that force it to follow the same growth-pathway; and, on the other hand, they are governed by a quite standardized operation of hierarchical integration. In that, each level of linguistic awareness has to incorporate the preceding level and extend further. This operation takes the form of hierarchical, substituting phases, and standard, invariable organization that governs the cognitive development of all children. In addition, it is guided by the principle of subordination, meaning that the development of semantic awareness is subordinated to operational structures.

It is worth mentioning that a number of psycholinguistic scholars adopted the Piagetian unilateral approach in dealing with semantic awareness. Such researchers were: Herriman (1986), who stressed that linguistic awareness is subject to operational structures; Smith (1979) who stated that the emergence of semantic awareness is dependent on the child's ability to accessing the stage of formal operations. Similarly, many studies tried to prove the existence of whole structures through revealing the significant correlation between child's

success in some Piagetian tasks (namely, inclusion, serial arrangement, and conservation, among others) and progress in semantic awareness (Hakes, 1980; Tunmer & Fletcher, 1981).

Flavell (1978) was also influenced by this Piagetian view and stressed that both operational thinking and linguistic awareness were expression of a general change undergone by the cognitive system, represented by the formation of the meta-cognitive domain.

Berthoud-Papandropolou (1980) challenged some Piagetian concepts in that this researcher claimed that the meta-linguistic growth is not part of the growth of logical structures, and cannot be included within whole structures, believing that there is some sort of parallelism between the meta-linguistic pathway and the logical-mathematical pathway. As such, the development of the child's word-concept is likely to interact with the formation of such cognitive skills as numeration, conservation, serialization and inclusion, among others. Furthermore, the development of linguistic awareness is achieved through a linear progressive and sustained pathway that eventually enables the child to become an expert, and this through consecutive phases of evolution.

A number of facts in the experiments within the scope of the present study indicate that the unilateral approach failed to explain the mentalist word theory's growth and function.

These facts are:

The development of the skill of distinguishing between linguistic appearance and linguistic reality is not achieved through a linear, progressive and sustained pathway. As a matter of fact, even young children have the same linguistic abilities as older ones, concerning some specific domains. This undermines the unilateral claim that the child's linguistic awareness improves constantly through a progressive and sustained growth pathway that goes up from lack of meta-linguistic expertise to the attainment of such an expertise.

The growth pathway of evaluating false belief competence is not subject to a sustained increase rate solely but also to other rhythms or rates of growth (such as regressions or stagnations) and this observation makes our findings incompatible with the unilateral principle of the "hierarchical growth".

The multi-variability principle, which is a fundamental principle of the mentalist word theory, differently from the essential unilateral paradigm of single-factor theories which imply the rule of "whole structures", implies the existence of intra-individual variability (that is to say, the variation in performance for the same subjects from the first task to the second task), of inter-individual variability (that is to say, in our case, the presence of inter-individual differences within all age groups younger than seven years in the task of the false belief on word-concept), and of cross-cultural variability (that is to say, the discrepancy between our results and those of a number of Western studies, especially the fact that we found that the child may become aware of the word-concept at an age much earlier than the one claimed by other studies).

Thus, we have to admit that the unilateral paradigm is limited in explaining "real-world" phenomena, and cannot adequately explain the formation of the mentalist word theory. As such, it should be replaced by another paradigm that is much more open and much more efficient. This is the pluralistic paradigm.

Indeed, many studies have approached the formation of the word-concept within the pluralistic paradigm that we advocate. Some studies have, in fact, concluded that this formation is subject to intra-individual variability and that it is not limited to a progressive and sustained pathway but is also subject to periods of recession (Bassono, Eme & Maillachon, 1999).

Other scholars have stressed the important role of inter-contextual variability in the development of the child's word-concept awareness. Karmiloff-Smith et al. (1996) maintained the role of word-concept awareness of the child in particularly suspenseful situations (for example, while a story is being narrated, the narrator pauses and asks the subject to recall the last word he/she heard) and concluded that the child may become aware of the word-concept at the pre-school phase; in other words, at an age much earlier than what Berthoud-Papandropolou (1980) claimed.

We would like to notice here that one of the exciting conclusions of Karmiloff-Smith et al. (1996) is that four-year-old subjects with a percentage of 75% and five-year-old children with a percentage of 95% considered the open-class words (like adjectives, nouns, verbs) and the closed-class words (such as conjunctions, prepositions) as words.

In our study, we also recorded that the child demonstrates a number of meta-linguistic abilities before the age of eight years – earlier than the age claimed by Berthoud-Papandropolou (1980); such ability is demonstrated by the fact that he/she considers the adverbial particle “*qorbal*” (meaning “near” in Arabic language) as a word. Another proof is his/her awareness at five years of age of the arbitrary relationship between names and their references (in the “*Dirham*” item or in the Alice in Wonderland task).

As is the case with Karmiloff-Smith (1980), the main reason for the emergence of such meta-linguistic competence within our data is the type and nature of our tasks, which take the form of game-like scenarios. This enables subjects to feel happy, relaxed and perfectly at their ease, especially with the Alice in Wonderland task. In this manner, we were able to discover the child's meta-linguistic competence through an indirect path and, most importantly, at an earlier age than other researchers.

We decided not to adopt the Berthoud-Papandropolou's task that takes the form of school-like and direct questions (such as “What does the word “word” mean to you?”) or explicit instructions (like “Give me an example of a long word”). Such questions ended up positioning the child in inappropriate context and this caused the researcher to discover the child's linguistic awareness at a later age than we did. Thus, we believe that the child's mentalist word theory varies according to the nature of the tasks used. Hence, the important role of inter-contextual variability.

In spite of the small margin of inter-individual variability recorded within the experiment of this study, a number of pluralistic researchers have, in fact, recorded the importance of this factor in the acquisition, formation and development of the child's word-concept. These researchers include well-known scholars, such as Bassano (1999), Fenson (1994, cited by Karmiloff-Smith, 1997) and Keznick (1997, cited by Karmiloff-Smith, 1997a).

We think it would be inappropriate to use the data in this study to build up cross-cultural or inter-lingual comparisons as there is the absence of the homology in experimental conditions between our present study and other studies. However, this does not mean that we do not recognize the important role of cross-cultural and inter-lingual variabilities in the formation and refinement of the child's word-concept.

As such, we agree with many studies like the investigation performed by Gopnik and Choi (1995) or by Bassano (1999) when it is stated that the cross-cultural and inter-lingual variabilities play a major role in the evolution of the child's mentalist word theory.

To conclude, on the basis of our experimental data and given the extant scholarly literature, the mentalist word theory appears to be a complex, variable phenomenon. Indeed, the data emerged from our experiments are of invaluable significance with regards to intra-

individual and inter-contextual variabilities. Such types of variability are more than sufficient to deny the universality claim and rather reinforce the value of pluralistic theories and models. However, in spite of the fact that the mentalist word theory is variable and relative, it still is possible to draw local pathways of its evolution based on our current data.

4.3.2. The Coalition Aspect in the Formation of the Mentalist Word Theory

Our data seem to strongly indicate that the development of the mentalist word theory is achieved through a course of conceptual changes that enables the child to eventually transform naïve knowledge into scientific knowledge.

We would like to stress that this is not realized all at once, but rather *via* a lengthy process that goes through an intermediate phase where the child tries to combine together his/her naïve beliefs and the scientific knowledge, which he/she most often learns at school, in order to build up some sort of a synthetic theory, thus giving rise to an original syncretism.

Hence, the course of conceptual changes in language is rather similar to conceptual changes occurring in the domains of Physics and Astronomy (Ioannides, & Vasniadou, 2002). In other words, the child does not abolish his/her primitive linguistic knowledge all at once but rather combines it with the new inputs to formulate some sort of new, hybrid theories (Carey & Johnson, 2000).

In addition to the coalition mechanism used by the child during the course of conceptual changes, he/she also uses and exploits the differentiation mechanism. The use of the latter mechanism is not restricted to the formation of concepts in Mathematics and Physics as indicated by some researchers (discriminating the hot from the warm, force from energy) (Carey 1991, Ioannides, & Vasniadou, 2002) but is also of significant relevance to the formation of the word-concept.

This is clearly demonstrated by the fact that low-level pupils in the experiments carried out in our study consistently confused words, letters and spelling (writing). For example, in the replies to the “train” item task, we received replies like “I have chosen the word */asdiqae/*” (meaning “friends” in Arabic language) because it is longer to write, ... because it contains a lot of words [instead of letters]”. At a more advanced level, we got justifications as “The word */asdiqae/*” (meaning “friends” in Arabic language) represents the longest word in the given sentence, because it contains a larger number of letters”.

Schooling has a very influential role convincing the child to give up to his/her naïve and even to his/her complex theories for embracing scientific knowledge. The important role of the schooling factor is clearly demonstrated by the outstanding variability between the answers given by kindergarten pupils and those by pupils at more advanced levels.

Thus, we emphasize that without schooling there may be no real progression of conceptual changes and the subject would undoubtedly limit himself/herself to his/her naïve word theory.

In this respect, Kolinsky, Carey & Morais (1987) concluded that illiterate adults tend to have the same level of semantic awareness of primary school pupils. We would like to add that this conclusion is not specific to the mentalist word theory but is also pertinent (for example) to the formation of the naïve astronomical theory. As a matter of fact, the representations of illiterate adults about the earth’s roundness (sphericity) and other astronomy-related concepts are rather similar to those of a young pupil (Vosniadou, 2007).

The reality is that kindergarten pupils do have a naïve word theory that enabled them to deal with the task of distinguishing linguistic appearance *versus* linguistic reality. This pre-

built knowledge is gradually developed, built, refined, expanded and guided by pseudo-innate and specialized principles (Karmiloff-smith, 1992).

On the whole, various factors contribute to the formation of the mentalist word theory:

- Innate/pseudo-innate knowledge.
- Acquired knowledge (learned either at school or out-of-school).
- The dynamics of the internal cognitive system.

Hence, as Hollich et al. (2000) argued in their coalition model, the child may use multiple cues in his/her endeavor to acquire, develop and refine the word-concept.

CONCLUSION: VALIDITY AND LIMITATION OF THE HYPOTHESES

We conclude that the mentalist word theory with a unilateral approach (Herriman, 1981; Smith, 1979; Berthoud-Papandropolou, 1980) fails to explain “real-world” phenomena.

1) On the contrary, the variability of the mentalist word theory is demonstrated by:

- The growth pathways not subject to linear, progressive and sustained growth rates but (also) subject to periods of stability, regression and recessions.
- Intra-individual variability as demonstrated by the performance of examinees that varies with the task of false belief about word-concept on one hand and the task of distinguishing between linguistic appearance *versus* linguistic reality on the other hand.
- Inter-contextual variability as demonstrated by the fact that a slight modification of the task enables us to get results that are different from those of other studies. Indeed, facilitating the task and making it more appropriate enables us to discover the child’s meta-linguistic activity at an age much earlier than what Berthoud-Papandropolou (1980) specified.
- Cross-cultural and inter-lingual variability: for the sake of scientific validity we would specify that our data are insufficient to measure the extent of these two types of variability. As such, further research is warranted.

2) The coalition dimension in the evolution of the mentalist word theory.

To summarize, we can say that the mentalist word theory is built through a course of conceptual changes. This progression is a coalition activity that involves a number of different factors: namely, innate/pseudo-innate knowledge, knowledge learnt and acquired both at school and out-of-school, and the complex dynamics of the cognitive system.

Chapter 16

VERBAL GRAMMAR CORRELATION INDEX (VGCI) AS A TOOL OF COMPARATIVE LINGUISTICS

*Alexander Akulov**

Saint Petersburg, Russia

ABSTRACT

Method of comparative linguistics based on comparison of lexis allows making different conclusions about the genetic classification of the same language. When different conclusions are based on the same methodology it is the best evidence that such methodology (comparison of lexis) is irrelevant. Language isn't a heap of lexemes, but is ordered pair $\langle A; \Omega \rangle$ where A is set of grammatical meanings and Ω is set of positional distributions defined upon A . On the base of such understanding of language was elaborated Verbal Grammar Correlation Index (VGCI). The main idea of VGCI is simple: more closely related languages have more alike sets of grammatical meanings and their common meanings are distributed in more alike positions, so the index of correlation of more closely related languages is higher. VGCI is the direct comparison of languages which exist/existed in reality. VGCI works with pure structures (it doesn't use any reconstructions or comparison of material exponents). Tests of VGCI on the material of firmly assembled stocks (Austronesian; Indo-European; Sino-Tibetan) showed the following: if value of VGCI is about 0.4 or higher it means that compared languages are related; if value of VGCI is about 0.3 or lower it means that compared languages aren't related. With use of VGCI have been found relatives of Ainu language (Great Andamanese language and Sino-Tibetan stock) and has been proven relatedness of Austronesian and Austroasiatic stocks. VGCI can be extremely useful in the fields of genetic classifications of indigenous languages of the Americas, Papuan languages and Australian Aboriginal languages.

Keywords: comparative linguistics, Verbal Grammar Correlation Index, typological methods in comparative linguistics, Ainu, Andamanese, Austronesian, Austroasiatic, Sino-Tibetan

1. INTRODUCTION TO THE PROBLEM

In contemporary linguistics can be seen an obsession of discovering the relationship of certain languages by comparison of lexis and an obsession to separate analysis of structures from historical linguistics. The main problem of all hypotheses of so called distant relationship is that it is not based on any firmly testable method, but just on certain particular views and on “artist sees so” principle. Tendency to think that typology should be separated from historical linguistics was inspired by Joseph Greenberg in West and Segrei Starostin and Nostratic tradition in USSR/Russia. Despite followers of Nostractics insist that their methods differ from those of Greenberg, but actually their methods are almost the same: they take word lists, find some look-alike lexemes¹ and on the base of these facts conclude about genetic relationships of certain languages. Followers of Greenberg and Starostin consider typological studies as rather useless glass bead game. Typological items are never considered as a system by adepts of megalocomparison²; usually some randomly selected items are taken outside of their appropriate contexts. For instance, active or ergative typology, or the fact of so called isolating or polysynthetic typology (i.e., items that are unusual in the native languages of researchers and that shock researchers’ minds) are considered as interesting exotic items, while no attention is paid to holistic and systematic analysis of language structures. Such approach makes typology be a curiosity store, but not a tool of comparative linguistics. However, according to founding-fathers of linguistics, typology should be the main tool of historical linguistics. According to the mythology created by adepts of megalocomparative linguistics has actually little connection with typology and makes its statements by the use of a lexicostatistical hoodoo. Often megalocomparativists object on such critics saying that they also pay attention to structural issues and also compare morphemes. Actually the megalocomparative comparison of morphemes is analysis in a lexical way, i.e., only material implementations of morphemes are compared, so there is no difference between such comparison and comparison of lexemes. The fact that any morpheme consists of three components (meaning, position and material implementation) is ignored; and morphemes are actually reduced to their material components. Almost no attention is paid to the fact that grammar is first of all positional distribution of certain meanings. There is a presupposition that genetic relationship of two languages can be proved by discovering of look-alike lexemes of so called basic vocabulary and by finding out certain regular phonetic correspondences.

So called “basic vocabulary” is actually a badly defined issue; there are no clear criteria which could determine: what lexis belongs to so called “basic lexicon” and what doesn’t. So called “basic lexicon” is actually culturally determined (Hoijer 1956) and borrowings can be inside it. Any scholar who uses the methodology of lexicostatistics actually can determine basic vocabulary according to certain particular wishes arbitrarily widening or narrowing it: if there is a need to show relatedness “basic vocabulary” can be narrowed, if there is a need to show that compared languages aren’t related “basic vocabulary” can be widened, and particular conclusions seriously depend on the preferences of particular scholar. When I say

¹ Nobody actually cares that sometimes certain lexemes can look alike just by coincidence: the shorter certain lexeme is, the higher is the probability that there can be randomly alike lexemes with close meanings in some other languages.

² Megalocomparison is a term invented by James Matisoff (Matisoff 1990); the term is used to denote attempts to discover the relationship of certain languages by so called “mass comparison” of lexis.

that “artist sees so” principle is the base of lexicostatistics it isn’t a figure of speech it’s nothing else, but just ascertaining of a fact.

However, yet Atoine Meillet pointed at the fact that regular phonetic correspondence can appear due to borrowings and can’t be proofs of relationship:

Grammatical correspondences provide proof, and they alone prove rigorously, but only if one makes use of the details of the forms and if one establishes that certain particular grammatical forms used in the languages considered go back to a common origin. Correspondences in vocabulary never provide absolute proof, because one can never be sure that they are not due to loans (Meillet 1954: 27).

Regular phonetic correspondence can be between words of any randomly selected languages. For instance, it is possible to find some regular correspondence between Japanese and Cantonese and even “prove” their relationship: *boku* Japanese personal pronoun “I” used by males – Cantonese *buk* “servant”, “I”; Japanese *bō* “stick” – Cantonese *baang* “stick”; Japanese *o-taku* “your family”, “your house” or “your husband” – Cantonese *zaak* “house”; Japanese *taku* “swamp” in compounds – Cantonese *zaak* “swamp”; Japanese *san* “three” – Cantonese *sam*; Japanese *shin* “forest” used in compounds – Cantonese *sam* “forest”; Japanese *roku* “six” – Cantonese *lūk*; Japanese *ran* “orchid” – Cantonese *laan* “orchid”. If there would be no other languages of the so called Buyeo³ group and no languages of Chinese stock we would have no ability to single those words as items borrowed from Southern Chinese dialects since they have same regular and wide use as words of Japanese origin. In the case of Japanese and Cantonese we know history of their stocks rather well and have many firm evidences that Japanese isn’t a relative of Chinese stock

If someone thinks that this example about Japanese and Cantonese is just an odd joke, then everyone can take a look at the procedure that was used by Greenberg in order to prove that Waikuri language belonged to Hokan family⁴: the conclusion that Waikuri belonged to Hokan stock was based on comparison of FOUR (!) words only (Poser, Campbell 1992: 217 – 218). Also, we should keep in mind that Greenberg actually didn’t care much about precise phonetic correspondences and superficial likeness was rather sufficient for him.

Phonetic correspondences can be even between unrelated languages and so a stock can’t be proved by regular correspondences, but regular correspondences should be proved by the existence of a stock since truly regular phonetic correspondences exist only inside stocks.

A methodology that ignores structural/grammatical issues allows different scholars to make completely different conclusions about the same language, for instance: Sumerian is thought to be a relative of Uralic stock (Pärpola 2007), or Sino-Tibetan (Braun 2001, 2004), or Austroasiatic (Diakonoff 1997). Another notable example is Ainu that is attributed to Altaic (James Patrie 1982), to Austronesian (Murayama Shichirō 1993), to Mon-Khmer (Vovin 1993)⁵. The most notable fact is that all such attempts coexist and all are considered by public as rather reliable in the same time. It looks much alike a plot for a vaudeville sketch

³ Buyeo stock is conventional name of a group that includes Japanese, Korean and Ryukyuan languages. Close relatedness of Japanese and Korean has been proven in Akulov 2016.

⁴ Waikuri is an extinct language that existed in Southern part of Baja California (pic 1). Hokan stock is a hypothetical stock of a dozen small language families that were spoken mainly in California, Arizona and Baja California (pic 1).

⁵ Ainu is especially attractive material for perfunctory and naïve hypotheses.

rather than a serious matter of a science. Different methods can lead to different conclusions, but if people use same methodology they supposedly are expected to make same conclusions about the same material, however, we don't see it; it means only that methodology based on comparison of lexis is a completely irrelevant method for historical linguistics.

The main function of any language is to be an instrument of communication, but in order to be able to communicate first of all we have to set a system of rubrics/labels/markers, that's why the main function of any language is to rubricate/to structurize reality. Structural level/grammar is the mean that rubricates reality and so it is much more important than lexicon. I suppose we can even say that structure appeared before languages of modern type, i.e., when the ancestors of *Homo sapiens* developed possibility of free combination of two signals inside one "utterance" it had already been primitive form of modern language. Structure is something alike bottle while lexicon is liquid which is inside the bottle; in a bottle can be put wine, water, gasoline or even sand but bottle always remains the same.

To those who think that structure is not important I can give the following example: *Gakusei ha essei wo gugutte purinto shita*. "Having googled an essay student printed [it]". What makes this phrase be a Japanese phrase? Words *gakusei* "student" (a word of Chinese origin), *essei* "essay" (a word of English origin), *purinto* "print" or, may be, "Japanese" verb *guguru* "to google"?

Figure 1. Geographic location of Waikuri language and hypotheticalal Hokan stock.

All the above considered facts mean that comparison of lexis should not be base of genetic classification of languages and any researches about genetic affiliation should be based on comparative analysis of grammar, i.e., comparison of grammatical systems is completely obligatory procedure to prove/test some hypothesis of genetic affiliation of a language.

2. A DESCRIPTION OF THE METHOD

2.1. General Theoretical Background of the Method

Language is first of all grammar. Grammar is ordered pair of the following view: $\langle A; \Omega \rangle$ where A is set of grammatical meanings and Ω is set of positional distributions defined upon A .

It is possible to estimate the degree of proximity of grammars by estimation degrees of proximities of sets of grammatical meanings and sets of positional distributions and then take superposition of both indexes.

It is rather obvious that the more closely related are certain languages the higher value of the correlation index they demonstrate: languages which are closer relatives have more common grammatical meanings and these common meanings have more alike positional implementations; languages which are more distant relatives have less common grammatical meanings and these common meanings demonstrate less alike positional implementations.

2.2. The Main Idea of the Method and Its Value for Comparative Linguistics

It was supposed that there was certain threshold value of the correlation index that determined the borders of stocks, i.e., if certain particular value of the correlation index is higher than the threshold, then compared languages are relatives, if certain particular value is lower than threshold value then compared languages are not related.

It was supposed that having compared distant relatives of firmly assembled stocks it could be possible to detect the threshold value of the correlation index (i.e., value of the correlation index that demonstrated distant relatives) and then this threshold could be applied to languages with unsettled genetic affiliation in order to see whether they were related to certain other languages.

And threshold value has been detected after comparison of distant relatives belonging to such firmly assembled stocks as: Austronesian, Austroasiatic, Indo-European and Sino-Tibetan (see 2.6).

Should be specially noted that the method is intended to make a direct comparison of languages that exist/existed in reality, i.e., it doesn't suppose any use of reconstructions which often are much alike constructed languages since they in many cases are determined by particular preferences of authors and can't be verified anyhow.

Also should be noted that the method doesn't pay any attention to material implementations at all, i.e., the method supposes comparison of meanings and their positional distributions only. It isn't a response to radical adepts of lexicostatistics who harshly ignore

issues of grammar, but it just a practical matter of reality since material correlation (regular phonetic correspondences) between languages which are distant relatives can be a very complicated matter, so the method is intended to prove genetic relationship/unrelatedness only by the comparison of sets of meanings and by comparison of their positional distributions.

The last point is especially important in the case of comparison of Sumerian with certain other languages. Sumerian phonology is not even a reconstruction, but is just a very approximate rough imagination based on Sumerian-Akkadian dictionaries. The case of Sumerian is this very issue where any comparison of material implementations should be completely eliminated and where any conclusions about possible relationship should be made on the analysis of pure structures only.

2.3. Why the Method Is Based on Comparison of Verbal Grammar?

Why it is supposed that it is possible to conclude about the relatedness of certain languages considering only verbal grammar? It is possible because verbal grammar is much more universal than the grammar of noun. There are many languages which have almost no grammar of noun while there is no language without verbal grammar, i.e., there are languages which have no cases and genders, but there are no languages without modalities, moods, tenses and aspects (even language that are very close relatives can differ seriously in that case, for instance: English and German or Russian and Bulgarian). That's why the verb is considered as the backbone of any grammar and backbone of the comparative method.

2.4. Whether Is It Possible to Prove Genetic Unrelatedness of Certain Languages?

An important point of current consideration is the possibility to prove unrelatedness of certain languages.

The possibility to prove unrelatedness is a necessary tool of any classification as well as possibility of proving of relatedness. If there would be no possibility to prove unrelatedness then even a single stock hardly could be assembled since it would not be possible to detect certain languages which don't belong to this stock.

Possibility of proving of unrelatedness is discussed and proved in the following papers: Akulov 2015b; Brown 2015.

Relatedness/unrelatedness is an equivalence relation since it meets necessary and sufficient requirements for a binary relation to be considered as equivalence relation:

1. Reflexivity: $a \sim a$: a is related with a ;
2. Symmetry: if $a \sim b$ then $b \sim a$: if a is related with b then b is related with a ;
3. Transitivity: if $a \sim b$ and $b \sim c$ then $a \sim c$: if a is related with b and b is related with c then a is related with c .

If it has been proved that an x language belonging to X stock is related/unrelated to y language belonging to Y stock then it means that x is related/unrelated to the whole Y stock and that whole stocks X and Y are correspondingly related/unrelated.

Thus, can be resumed the following:

- a) Relatedness means “language belongs to a stock”; unrelatedness means “language doesn’t belong to a stock”.
- b) If set of 234 classes/stocks⁶ has been set up, then it obviously supposes that there should be a possibility of classification, i.e., we can say whether a language belongs to a stock; moreover, we always can show some languages which don’t belong to certain stock. If possibility to prove unrelatedness is denied then we actually can’t establish scopes of stocks and can’t distinguish one stock from another; then even a single stock hardly could have been assembled.

Any two randomly selected languages can be related or not related, i.e., there can be no ‘third variant’ since relatedness/unrelatedness supposes the existence of classes which don’t intersect. If a language of X stock is related to a language of Y stock it means that these stocks are related.

2.5. The Algorithm of Calculation of Verbal Grammar Correlation Index (VGCI)

2.5.1. An Abstract Scheme of VGCI Calculation

Let’s imagine two abstract model languages: X and Y.

X is described by the following sets:

A_X (set of grammatical meanings of X) is the following: $\{x_1, x_2, x_3, x_4, x_5, x_6\}$;

Ω_X (set of positional distributions of grammatical meanings of X) is the following:

$\{x_1 \rightarrow p_1; x_2 \rightarrow p_1, p_2; x_3 \rightarrow p_2, x_4 \rightarrow p_2, p_3; x_5 \rightarrow p_4, x_6 \rightarrow p_5\}$

Y is described by the following sets:

A_Y (set of grammatical meanings of Y) is the following: $\{y_1, y_2, y_3, y_4, y_5\}$

Ω_Y : (set of positional distributions of grammatical meanings of Y) is the following:

$\{y_1 \rightarrow p_1; y_2 \rightarrow p_1, p_2; y_3 \rightarrow p_2, y_4 \rightarrow p_5, p_3; y_5 \rightarrow p_4\}$

It is possible to estimate degree of correlation between X and Y by the following way:

- 1) estimate degree of correlation between A_X and A_Y (to do it we have to find intersection of A_X and A_Y and then take intersection ratio to the number of elements of each set and then take arithmetical mean of both ratios);

⁶ According to Ethnologue nowadays there are 234 language stocks/families (Ethnologue 2016).

- 2) estimate degree of correlation of positional distributions of common grammatical meanings (i.e., meanings belonging to intersection of A_X and A_Y);
- 3) take superposition of two indexes since lists of grammatical meanings and lists of positional distributions should be correlated in the same time.

The degree of correlation A_X and A_Y is the following: intersection of A_X and A_Y is $\{y_1, y_2, y_3, y_4, y_5\}$, let's suppose that all elements of A_Y are correlated by one-to-one correspondence with first five elements of A_X , so intersection consists of 5 elements and thus the ratios of elements belonging to the intersection to the numbers of elements of A_X and A_Y are the following: $5/6$ and $5/5$, and then the arithmetical mean of both ratios is the following: $(5/6 + 5/5)/2 \approx 0.9$.

Degree of correlation of positional distributions of grammatical meanings belonging to intersection of A_X and A_Y is estimated by the following way:

- $x_1: p_1 \leftrightarrow y_1$: p_1 positional distributions are identical so index of correlation is 1
 $x_2: p_1, p_2 \leftrightarrow y_2$: p_1, p_2 positional distributions are identical so index of correlation is 1
 $x_3: p_2 \leftrightarrow y_3$: p_2 positional distributions are identical so index of correlation is 1
 $x_4: p_2 \neq y_4$: p_5 positional distributions are dissimilar so index of correlation is 0
 $x_5: p_4 \leftrightarrow y_5$: p_4 positional distributions are identical so index of correlation is 1

And then to estimate degree of positional correlation we should take sum of all particular indexes of positional correlation and take their arithmetical mean: $(1 + 1 + 1 + 0 + 1)/5 = 0.8$.

Then in order to get the final index of correlation of X and Y we have to take superposition of two indexes since lists of grammatical meanings and positional distributions both should be correlated simultaneously, i.e., we have to multiply two indexes, in current case it gives the following value: $0.9 \cdot 0.8 = 0.72$.

Thus resuming the above said it is possible to represent scheme of calculation of index of correlation by the following formula:

$$\left(\frac{N_{e(A \cap B)}}{N_{e(A)}} + \frac{N_{e(A \cap B)}}{N_{e(B)}} \right) \frac{1}{2} \times \left(\frac{i_1 + i_2 + \dots + i_n}{N_{e(A \cap B)}} \right)$$

A is set of grammatical meanings of one language;

B is set of grammatical meanings of another language;

N_e means amount of elements;

i means index of positional correlation of certain common meaning.

2.5.2. An Example of VGCI Calculation: Comparison of English and Russian

First of all we need to take the list of grammar meanings of both compared languages (in current case of English and Russian).

I am to note that in current text I pay attention mostly to so called contentive grammatical meanings. i.e., not to, for instance, markers of transitivity, but to such items as: markers of tenses, aspects, modalities and so on, i.e., to those grammatical categories which have certain content that can be expressed by lexical means.

As far as it can be a rather complicated task to distinguish obligatory features of certain verb from facultative so first of all attention should be paid to the following categories:

- a) tenses and aspects;
- b) mood and modalities;
- c) voices;
- d) agent, patient, object, subject.

Also, there can be certain specific categories like, for instance: markers of evidentially (a kind of modality), or spatial orientation/versions (can be considered as a development of triggers system), that's why good descriptions are matters of high importance (however, often same items can be described by different terms).

In every language usually there are about 20 – 40 grammatical meanings expressed in the verb, so actually the list of possible meanings is rather compact and all meanings can be surveyed rather easily. This is one of important and substantial differences of this methodology from methodology based on comparison of lexis since in the case of lexis it's almost impossible to determine border of so called basic lexicon and much depends on particular preferences of certain authors.

2.5.2.1. The List of English Grammatical Meanings Expressed in the Verb with Their Positional Implementations

The list of English grammatical meanings expressed in verb and their positional implementations has been compiled after Barhkhudarov et al. 2000.

1. Active voice: zero marker
2. Agent: prp- / [prp-] * 6 -sfx⁷
3. Causative: prp-
4. Conditional mood: prp-
5. Deontic modality: prp-₁/prp-₂/prp-₃/prp-₄
6. Desiderative: prp-₁/prp-₂
7. Future continuous: prp + prp + -sfx
8. Future perfect: prp- + prp- + inner fusion/prp- + prp+ -sfx
9. Future perfect continuous: prp + prp + prp- + -sfx
10. Future simple: prp-
11. Hortative: prp-
12. Imperative: R (zero marker)
13. Impossibility: prp-
14. Indicative: zero marker
15. Interrogative: prp-
16. Negation: prp-
17. Optative: prp-
18. Passive voice: prp- + -sfx/prp- + inner fusion

⁷ In such way of recording only syntagmatically different elements are taken into account so while elements that belong to the same paradigm are generally considered as variants of the same element, for instance: prepositional way of expression of agent in English supposes an endless set of elements (personal pronouns, names, nouns) but from the syntagmatic point of view they all are just particular realizations of the same item.

19. Past continuous: prp + -sfx
20. Past simple: inner fusion/suppletion/-sfx
21. Past perfect: prp + -sfx/prp + inner fusion
22. Past perfect continuous: prp- + prp + -sfx
23. Patient: -pp
24. Plural number: prp-/ [prp-] * 3 -sfx
25. Possibility: prp-
26. Present continuous: prp- * -sfx
27. Present perfect: prp- + -sfx/prp + inner fusion
28. Present perfect continuous: prp- + prp + -sfx
29. Present simple: 6 -sfx
30. Prohibitive: prp-₁/prp-₂
31. Singular number: prp-/ [prp-] * 3 -sfx
32. Subject: prp-/ [prp-] * 6 -sfx
33. Subjunctive mood: prp-

2.5.2.2. The List of Russian Grammatical Meanings Expressed in the Verb with Their Positional Implementations

The list of Russian grammatical meanings expressed in verb and their positional implementations has been compiled after Wade 2011.

1. Active voice: zero marker
2. Agent: [prp] * 6 -sfx
3. Attemptive aspect/mood: prfx-
4. Causative: prp-
5. Deontic modality: prp-₁/prp-₂/prp-₃
6. Desiderative: prp-₁/prp-₂
7. Feminine gender: -sfx
8. Future perfect: prfx-₁ * 6 -sfx/prfx-₂ * 6 -sfx/prfx-₃ * 6 -sfx/prfx-₄ * 6 -sfx/prfx-₅ * 6 -sfx/prfx-₆ * 6 -sfx/prfx-₇ * 6 -sfx/prfx-₈ * 6 -sfx
9. Future simple: prp- + -sfx/prfx- * 6 -sfx
10. Indicative: zero marker
11. Imperative1: -sfx₁/-sfx₂/-sfx₃/inner fusion + -sfx₁
12. Imperative2: -sfx₁ + -sfx/-sfx₂ + -sfx/inner fusion + sfx₁ + -sfx
13. Impossibility1 prp-
14. Impossibility2 prp-
15. Indicative mood: zero marker
16. Interrogative: prp-
17. Masculine gender: -sfx (zero suffix)
18. Negation: prp-
19. Neutral gender: -sfx
20. Passive voice: prp- + -sfx
21. Past simple: -sfx/suppletion + -sfx
22. Past perfect: prfx-₁ + -sfx/prfx-₂ + -sfx/prfx-₃ + -sfx/prfx-₄ + -sfx/prfx-₅ + -sfx/prfx-₆ + -sfx/prfx-₇ + -sfx/prfx-₈ * 6 -sfx/prfx-₁ + suppletion + -sfx/prfx-₂ + suppletion + -

- sfx/prfx-₃ + suppletion + -sfx/prfx-₄ + suppletion + -sfx/prfx-₅ + suppletion + -sfx/prfx-₆ + suppletion + -sfx/prfx-₇ + suppletion + -sfx/prfx-₈ * suppletion * 6 -sfx
23. Patient: -pp
 24. Plural number: [prp-] * 3 -sfx
 25. Potential modality: prp-
 26. Present perfect: prfx-₁ + -sfx/prfx-₂ + -sfx/prfx-₃ + -sfx/prfx-₄ + -sfx/prfx-₅ + -sfx/prfx-₆ + -sfx/prfx-₇ + -sfx/prfx-₈ * 6 -sfx/prfx-₁ + suppletion + -sfx/prfx-₂ + suppletion + -sfx/prfx-₃ + suppletion + -sfx/prfx-₄ + suppletion + -sfx/prfx-₅ + suppletion + -sfx/prfx-₆ + suppletion + -sfx/prfx-₇ + suppletion + -sfx/prfx-₈ + suppletion * 6 -sfx
 27. Present simple: 6 -sfx / inner fusion * 6 -sfx
 28. Prohibitive: prp-₁/prp-₂
 29. Reciprocity: -sfx
 30. Reflexivity: -sfx
 31. Singular number: [prp-] * 3 -sfx
 32. Subject [prp-] * 6 -sfx
 33. Subjunctive mood: prp-

Each grammatical meaning is followed by certain schemes of letters and signs. These are notations representing general schemes of positional implementation of certain grammatical meaning.

Notations of positional implementations are the following: prp- – preposition; prfx- – prefix; -infx- – infix; crfx---crfx – circumfix; crp---crp – circumposition; -RR- – reduplication⁸; inner fusion – any irregular changes inside the root; suppletivism; R – root; -sfx – suffix; -pp – post position.

If there are some different forms of same positional implementations (i.e., forms used in different contexts) they are numbered the following way: prp₁-/prp₂-/prp₃- and distinguished by slash, however, they also can be marked by the following way, for example: 6 -sfx that means six different suffixes; positional elements that are components of the same implementation are expressed in the following way: prp- + -sfx.

If a certain positional element can optionally be omitted, then it is written in square brackets for instance: [prp-].

Notation of the following view: [prp-] * 6 -sfx means that there are 6 different suffixes expressing certain grammatical meaning and each of them can optionally be accompanied by a preposition.

This way of notation shows not absolute positions of grammatical meanings in a linear model of word form/linear model of phrase⁹, but their positions in relation to nuclear position, i.e., it doesn't matter what prefix is placed closer to the nuclear position and what is placed in a more distant position since for current tasks is necessary and sufficient information that certain meanings are expressed by positions placed to the left of the nuclear position.

⁸ Reduplication is interpreted as reiteration of root.

⁹ Can be spoken out the following objection: certain languages have no linear models of word forms as far as they have no morphology; however, I am to note that even with increasing the degree of analytism (i.e., when a language syntaxizes and grammatical meanings begin to be expressed by the means of syntax) the positional distributions of grammatical meanings in relation to the nuclear position remain the same in general, and thus it is possible to say that there is no much difference between morphology and syntax and it is possible to speak about linear model of word form/linear model of phrase.

Also should be specially noted that this way of notation just shows places and technical means of expressions of grammatical meanings, i.e., I don't care about 'school grammar', for instance, I am not interested in how many verbal stems there are in a certain language. I consider language as something alike dark box with many holes, and implementation of certain grammatical meaning is light appearing in some holes and my task is to record in what holes light appears and then compare recording of different boxes (i.e., different languages).

2.5.2.3. Estimation of Correlation of Grammatical Meanings Sets of English and Russian

1. Active voice
2. Agent
3. Causative
4. Deontic
5. Desiderative
6. Future perfect
7. Future simple
8. Imperative
9. Impossibility
10. Indicative
11. Interrogative
12. Negation
13. Passive voice
14. Past simple
15. Past perfect
16. Patient
17. Plural number
18. Potential modality
19. Present perfect
20. Present simple
21. Prohibitive
22. Singular number
23. Subject
24. Subjunctive mood

In the case of English and Russian we haven't met any serious problems with correlation of grammar meanings since both languages actually have rather alike grammatical systems, however, sometimes it can be rather complicated.

We have 24 common meanings (or relatively common, anyway we have to suppose some drift and backlash of meanings) so index of of correlation of sets of grammatical meanings is the following:

$$(24/33 + 24/33)/2 \approx (0.73 + 0.73)/2 = 0.73.$$

2.5.2.4. Estimation of Positional Correlation of Grammatical Meanings Intersection of English and Russian

Now should be estimated degree of correlation of positional implementations of common grammatical meanings singled out in 2.5.2.3.

Schemes of positional implementation will help us to do it: we take the schemes that have been drawn above and completely formally compare the set of positional schemes of each meanings; if there is no difference (positional schemes are the same or very close, for instance: prp- and prfx- is the same full correlation as prp- and prp-) then this point is counted as 1; if there is completely no correlation (for instance prp- and -pp) then we count it as 0, in other cases we estimate the degree of correlation.

System of recording is the following: first is name of a grammatical meaning that is common for both of compared languages (or meanings that are correlated), then is abbreviation of name of the first of compared languages (En for English and Rus for Russian, then first language schemes of expressions of this grammatical meaning, then sign of correlation “~” or anti-correlation “≠”, then abbreviation of the name of second language, then second language ways of expressions of the grammatical meaning and then number that expresses degree of correlation. If certain meaning can be expressed by some ways in such case schemes representing these ways are separated by slashes; if there are some similar items expressing the same meaning, for instance, some prepositions, then they are marked by lower index numbers.

1. Active voice: En: zero marker ~ Rus: zero marker 1
2. Agent: En: prp-/ [prp-] * 6 -sfx ~ Rus: [prp-] * 6 -sfx 0.75
3. Causative: En prp- ~ Rus: prp- 1
4. Deontic modality: En: prp-₁/prp-₂/prp-₃/prp-₄ ~ Rus: prp-₁/prp-₂/prp-₃ $(2/2 + 3/4)/2 \approx 0.87$
5. Desiderative: En: prp-₁/prp-₂ ~ Rus: prp-₁/prp-₂ 1
6. Future perfect: in En: prp- + prp- + -sfx/prp- + prp- + inner fusion ≠ Rus: prfx-₁ * 6 -sfx/prfx-₂ * 6 -sfx/prfx-₃ * 6 -sfx/prfx-₄ * 6 -sfx/prfx-₅ * 6 -sfx/prfx-₆ * 6 -sfx/prfx-₇ * 6 -sfx/prfx-₈ * 6 -sfx; 0.
7. Future simple: En: prp- ≠ Rus: prp- + -sfx/prfx- * 6 -sfx 0
8. Imperative: En: R ≠ Rus: -sfx₁-sfx₂-sfx₃/inner fusion + -sfx₁-sfx₁ + -sfx/-sfx₂ + -sfx/inner fusion + -sfx₁ + -sfx 0
9. Impossibility: En: prp- ~ Rus: prp₁-/prp₂- 0.75
10. Indicative: En: zero marker ~ Rus: zero marker 1
11. Interrogative: En: prp- ~ Rus: prp- 1
12. Negation: En: prp- ~ Rs: prp- 1
13. Passive voice: En: prp- + -sfx/prp- + inner fusion ~ Rus: prp- + -sfx 0.75
14. Past simple: En: inner fusion/suppletion/-sfx ~ Rus: -sfx/suppletion + -sfx $(1/3 + 1/2)/2 \approx 0.41$
15. Past perfect: En: prp + -sfx/prp + inner fusion ~ Rus:
prfx-₁ + -sfx/prfx-₂ + -sfx/prfx-₃ + -sfx/prfx-₄ + -sfx/
prfx-₅ + -sfx/prfx-₆ + -sfx/prfx-₇ + -sfx/prfx-₈ * 6 -sfx
prfx-₁ + suppletion + -sfx/prfx-₂ + suppletion + -sfx/prfx-₃ + suppletion + -sfx/
prfx-₄ + suppletion + -sfx/prfx-₅ + suppletion + -sfx/prfx-₆ + suppletion + -sfx/
prfx-₇ + suppletion + -sfx/prfx-₈ + suppletion * 6 -sfx $(1/2 + 1/16) \approx 0.28$

16. Patient: En: -pp ~ Rus: -pp 1
17. Plural number: En: prp-/ [prp-] * 3 -sfx ~ Rus: [prp-] * 3 -sfx 0.75
18. Potential modality: En: prp- ~ Rus: prp- 1
19. Present perfect: E: prp + -sfx/prp + inner fusion ~ Rus:
 $\text{prfx}_{-1} + \text{-sfx/prfx}_{-2} + \text{-sfx/prfx}_{-3} + \text{-sfx/prfx}_{-4} + \text{-sfx/}$
 $\text{prfx}_{-5} + \text{-sfx/prfx}_{-6} + \text{-sfx/prfx}_{-7} + \text{-sfx/prfx}_{-8} * 6 \text{-sfx}$
 $\text{prfx}_{-1} + \text{suppletion} + \text{-sfx/prfx}_{-2} + \text{suppletion} + \text{-sfx/prfx}_{-3} + \text{suppletion} + \text{-sfx/}$
 $\text{prfx}_{-4} + \text{suppletion} + \text{-sfx/prfx}_{-5} + \text{suppletion} + \text{-sfx/prfx}_{-6} + \text{suppletion} + \text{-sfx/}$
 $\text{prfx}_{-7} + \text{suppletion} + \text{-sfx/prfx}_{-8} + \text{suppletion} * 6 \text{-sfx} (1/2 + 16) \approx 0.28$
20. Present simple: in En: 6 -sfx ~ Rus 6 -sfx/inner fusion * 6 -sfx 0.75
21. Prohibitive: En: prp₋₁/prp₋₂ ~ Rus: prp₋₁/prp₋₂ 1
22. Singular number: En: prp-/ [prp-] * 3 -sfx ~ Rus: [prp-] * 3 -sfx 0.75
23. Subject: En: prp-/ [prp-] * 6 -sfx ~ Rus: it is expressed as: [prp-] * 6 -sfx 0.75.
24. Subjunctive mood: En: prp- ~ Rus: prp- 1

Thus we have got the following indexes of positional correlation for each meaning of intersection:

1. Active voice: 1
2. Agent: 0.75
3. Causative: 1
4. Deontic: 0.87
5. Desiderative: 1
6. Future perfect: 0
7. Future simple: 0
8. Imperative: 0
9. Impossibility: 0.75
10. Indicative: 1
11. Interrogative 1
12. Negation: 1
13. Passive voice: 0.75
14. Past simple: 0.41
15. Past perfect: 0.28
16. Patient: 1
17. Plural number: 0.75
18. Potential modality: 1
19. Present perfect: 0.28
20. Present simple: 0.75
21. Prohibitive: 1
22. Singular number: 0.75
23. Subject: in 0.75
24. Subjunctive mood: 1

In order to calculate the index of positional correlation we have to take the sum of all these indexes and then take their arithmetic mean:

$$(10 + 0.87 + 7 * 0.75 + 0.41 + 2 * 0.28) / 24 \approx 0.71.$$

2.5.2.5. VGCI of English and Russian

And finally we should multiply index of positional correlation of common meanings by the index of meanings correlations since we want to know in what degree sets of meanings are correlated and in what degree intersection of sets of meaning is positionally correlated, i.e., we need both indexes to do intersection or conjunction, so we do the following: $0.71 \cdot 0.73 \approx 0.52$.

2.6. Threshold Values of VGCI

Tests of VGCI on the material of firmly assembled stocks have given us the following threshold values:

VGCI of English and Russian ≈ 0.52 ;
VGCI of English and Lithuanian ≈ 0.43 ;
VGCI of English and Latin ≈ 0.41 ;
VGCI English and Persian ≈ 0.38 ;
VGCI of Hawaiian and Lha'alua ≈ 0.39 ;
VGCI of Chinese and Tibetan ≈ 0.39 .

From other hand tests of VGCI on the material of unrelated languages have shown us the following:

VGCI (Chinese and English) ≈ 0.32 ;
VGCI (Chinese and Latin) ≈ 0.3 ;
VGCI (English and Tibetan) ≈ 0.13 .

If value of VGCI is about 0.4 or more than 0.4 then languages are related (i.e., belong to the same stock), if value of VGCI is about 0.3 or less than 0.3 then languages are not related. Such values as 0.39 and 0.38 also are variants of 0.4; while 0.31 or 0.32 are variants of 0.3. The more closely are related certain languages, the higher is value of corresponding VGCI.

2.7. Measurement Error

Test of measurement error shows that it is about 2% (Akulov 2015a: 37).

2.8. Estimation of the Probability of Coincidence

One can probably say that occasionally any two randomly selected languages can seem to be relatives. Let's think whether it is possible. Let's estimate the probability of such event. We have seen that intersections of sets of meanings are shaped by 15 – 24 elements. Let's suppose that each meaning is expressed by only one positional implementation that which can be chosen from following list of possible positional implementations:

1. prp-
2. prfx-
3. crp---crp
4. crfx---crfx
5. -infx-
6. -RR-
7. inner fusion
8. suppletion
9. R
10. -sfx
11. -pp
12. tr-sf-x

It is possible to say that prp- and prfx- and so on are actually very close and can modify this list:

1. prp- ~ prfx-
2. crp---crp ~ crfx---crfx
3. -infx-
4. -RR-
5. inner fusion
6. suppletion
7. R
8. -sfx ~ -pp
9. tr-sf-x

We have got 9 positions, but actually it would be more convenient to deal with a list of 10 positions so let's round the value we got and let's suppose there are 10 positions.

According to our above proposition we supposed that one meaning can be expressed only in one position. What is probability to choose coincidentally the same position as has been chosen by the same grammatical issue in another language? Imagine that you toss up a decahedron. What is probability that once certain face will appear? The probability is one tenth and it is same for any other faces. However, we have to get about 19 average positions simultaneously, so we have to multiply 0.1 by 0.1 nineteen times. The probability is 10^{-19} . Actually the real probability is much less than 10^{-19} since in current estimation has been counted only probability of positional correlation and has not been estimated and counted the probability of choice of similar sets of grammatical meanings. Anyway, this probability is very little, it is much less than, for instance, probability of meeting Earth with a truly dangerous asteroid that is about $2.5 \cdot 10^{-4}$ (the Earth exists about 4 milliard years and serious asteroids visit it about once per million years).

A more detailed description of VGCI method can be seen in Akulov 2015a.

3. VGCI PROVES THAT AINU ISN'T RELATED TO AUSTRONESIAN AND MON-KHMER STOCKS

3.1. VGCI Proves that Ainu and Austronesian Stock are Unrelated

Basing on comparison of some randomly chosen lexemes Murayama Shichirō wrote that Ainu is a relative of Austronesian stock (Murayama 1993). Let's check whether it is so by use of VGCI.

3.1.1. *Ainu and Lha'alua*

3.1.1.1. The List of Ainu Grammatical Meanings Expressed in the Verb with Their Positional Implementations

The list of Ainu grammatical meanings and their positional distributions has been compiled after Tamura 2000.

1. Agent: [prp-] * 7 prfx-
2. Causative -sfx
3. Deontic modality: -pp
4. Desiderative mood: -pp
5. Dubitative mood ~ evidentiality "may be": -pp
6. Evidentiality "people say": -pp
7. Evidentiality "speaker has seen it" -pp
8. Evidentiality "something can be heard/smelt" -pp
9. Evidentiality "something can be seen" -pp
10. Exclusive prfx-₁/prfx-₂/-sfx
11. Future conditional: -pp₁-pp₂
12. Future simple: -pp + -pp
13. Hortative: -pp
14. Imperative (plain): R (zero marker)
15. Imperative (polite): -pp
16. Impossibility: -pp
17. Inclusive: prfx-₁/prfx-₂/-sfx
18. Indicative mood: zero marker
19. Intensiveness: -RR-/sfx₁/-sfx₂/suppletion
20. Interrogative: -pp₁/pp₂
21. Iterative: -RR-/suppletion/-sfx₁/-sfx₂
22. Negation: prp-
23. Patient: [prp-] * 7 prfx-
24. Past simple: -pp
25. Past perfect: -pp
26. Plural number: [prp-] *10 prfx-/ [prp-] * 2 -sfx/[prp-] *10 prfx- * -sfx/prp- * -sfx *2 -sfx/[prp-] *10 prfx- * suppletion/[prp-] * suppletion * 2 -sfx/[prp-] *10 prfx- * -RR-/[prp-] * -RR- * 2-sfx

27. Possibility: -pp
28. Present continuous: -pp + -pp₁ / -pp + -pp₂
29. Present-future (general tense) zero marker
30. Present perfect: -pp
31. Prohibitive mood: prp-
32. Reason/intention: -pp
33. Reciprocity: prfx-
34. Reflexivity: prfx-
35. Singular number: [prp-] * 9 prfx- / [prp-] * 9 prfx- * suppletion
36. Subject: [prp-] * 5 prfx / 2 -sfx
37. Subjunctive mood “if”: -pp
38. Transitivity: prfx-
39. Undefined agent: prfx₋₁/prfx₋₂/prfx₋₃
40. Undefined causative -sfx

3.1.1.2. The List of Lha'alua Grammatical Meanings Expressed in the Verb with Their Positional Implementations

Lha'alua (or Saaroa) is one of Formosan languages; it belongs to Tsouic languages (see Figure 2). The list of Lha'alua grammatical meanings and their positional implementations has been compiled after Pan 2012.

1. Actor voice: prfx-/infx-/zero marker
2. Agent prfx-/ 6 -sfx
3. Attenuative/diminutive aspect aspect: -RR-
4. Causative: prfx-
5. Change of state aspect: -sfx
6. Durative aspect: -RRR¹⁰/-RR-
7. Evidentiality (reported evidentiality): -sfx
8. Exclusive: -sfx
9. Existential negation: prp-
10. Experiential aspect: prfx-
11. Habitual aspect: -RR-
12. Hortative: -sfx
13. Imperative 1: polite request -sfx
14. Imperative 2: strong request: prp-/sfx
15. Imperfective aspect -sfx
16. Inchoative: prfx-
17. Inclusive: -sfx
18. Indicative: zero marker
19. Interrogative: -sfx
20. Irrealis: prfx-/infx-/RR-
21. Iterative aspect: -RR-/ -RRR-
22. Locative trigger (locative voice) -sfx₁/-sfx₂/-sfx₃
23. Negation: prp-

¹⁰ -RRR- is the sign of triplication.

24. Patient trigger (voice): -sfx
25. Perfective aspect: prfx-
26. Plural number: prfx-/4 suffixes
27. Potential modality: -sfx
28. Prohibitive: prp-
29. Realis: zero marker
30. Singular number: prfx-/sfx₁/sfx₂/sfx₃
31. Uncertain modality: -sfx₁/sfx₂/sfx₃

Figure 2. Location of Lha'alua and Tsou languages upon the island of Taiwan.

3.1.1.3. VGCI of Ainu and Lha'alua

1. Agent: A.: [prp-] * 7 prfx- ~ Lh.: prfx-/6 -sfx $(1/7 + 1/7)/2 \approx 0.14$
2. Causative: A.: -sfx $\neq$ Lh.: prp- 0
3. Dubitative mood ~ Uncertain modality: A.: -pp ~ Lh.: -sfx₁/sfx₂/sfx₃ 0.66
4. Present continuous ~ durative: A.: -pp + -pp₁ / -pp + -pp₂ $\neq$ Lh.: -RR-/RRR- 0
5. Evidentiality "people say" ~ reported evidentiality: A.: -pp ~ Lh.: -sfx 1
6. Exclusive: A: prfx₁/prfx₂/sfx ~ Lh: -sfx 0.66
7. Future simple ~ irrealis: A.: -pp + -pp $\neq$ prfx-/infx-/RR- 0
8. Hortative: A.: -pp ~ Lh.: -sfx 1
9. Imperative (plain) ~ strong request: A.: R $\neq$ Lh.: prp-/sfx 0
10. Imperative (polite) ~ polite request: A.: pp ~ Lh. -sfx 1
11. Inclusive: A: prfx₁/prfx₂/sfx ~ Lh: -sfx 0.66
12. Indicative: A.: zero marker ~ Lh: zero marker 1
13. Interrogative: A.: -pp₁/pp₂ ~ Lh.: -sfx 1
14. Iterative: A.: -RR-/suppletion/-sfx₁/sfx₂ ~ Lh.: -RR-/RRR- $(\frac{1}{2} + \frac{1}{4})/2 \approx 0.37$

15. Negation: A.: prp- ~ Lh.: prp- 1
16. Plural number: A.: [prp-] * 10 prfx-/ [prp-] * 2 -sfx/[prp-] * 10 prfx- * -sfx/prp- * -sfx * 2 -sfx/[prp-] * 10 prfx- * suppletion/[prp-] * suppletion * 2 -sfx/[prp-] * 10 prfx- * -RR-/ [prp-] * -RR- * 2-sfx ~ Lh.: prfx-/4 -sfx $(3/48 + 3/5)/2 \approx 0.33$
17. Present-future tense ~ Irrealis: A: zero marker $\neq$ Lh: prfx-/ -infx-/ -RR- 0
18. Present perfect: A.: -pp $\neq$ Lh.: prfx.: 0
19. Possibility: A.: -pp ~ Lh.: -sfx 1
20. Prohibitive: A.: prp- ~ Lh.: prp- 1
21. Singular number: A: [prp-] * 9 prfx-/ [prp-] * 9prfx- * suppletion ~ Lh.: prfx-/ -sfx₁/ -sfx₂/sfx₋₃ $(1/18 + 1/4)/2 \approx 0.15$

Conspectus system of recording is the following: first is name of a grammatical meaning that is common for both of compared languages (or meanings that are correlated), then is abbreviation of name of the first of compared languages, then first language schemes of expressions of this grammatical meaning, then sign of correlation "~" or anti-correlation " $\neq$ ", then abbreviation of the name of second language, then second language ways of expressions of the grammatical meaning and then number that expresses degree of correlation. If certain meaning can be expressed by some ways in such case schemes representing these ways are separated by slashes; if there are some similar items expressing the same meaning, for instance, some prepositions, then they are marked by lower index numbers.

VGCI of Ainu and Lha'alua is the following:

$$(21/40 + 21/31)/2 * (7 + 0.75 + 3*0.66 + 0.37 + 0.14 + 0.33 + 0.15)/21 \approx 0.3.$$

Such value of VGCI is the same as that of unrelated languages (2.6).

Due to transitivity of unrelatedness (2.4) even comparison of Ainu with one Austronesian language is sufficient for proving unrelatedness, but for the sake of much visibility Ainu is also compared with Cham and Hawaiian.

3.1.2. Ainu and Cham

The list of Ainu grammatical meanings can be seen in 3.1.1.1.

3.1.2.1. The List of Cham Grammatical Meanings Expressed in the Verb and Their Positional Implementations

The list of Cham¹¹ grammatical meanings and their positional distributions has been complied after Alieva, Bui 1999 and Aymontie 1889.

1. Active: prp-
2. Agent: prp-
3. Causative: prfx₁/prfx₂-
4. Centrifugal orientation: -pp
5. Centripetal orientation: -pp
6. Desiderative: prp-
7. Durative aspect1: prp-

¹¹ Cham is an Austronesian language spoken in Southern Vietnam (pic 3, pic 4).

8. Durative aspect2: prp-
9. Future: prp-
10. General tense ~ general aspect: zero marker
11. Imperative: -pp
12. Interrogative: -pp
13. Indicative: zero marker
14. Iterative 1: -pp
15. Iterative 2: prfx-
16. Negation: prp₁-/prp₂-/crp---crp
17. Passive: prp₁-/prp₂-
18. Past simple: prp₁-/prp₂-/-pp
19. Patient: -pp
20. Perfect aspect 1: -pp
21. Perfect aspect 2: -pp
22. Perfect aspect 3: -pp
23. Plural number: prp-
24. Potential modality: -pp
25. Prohibitive: prp-
26. Reciprocity: prfx-/pp
27. Singular number: prp-
28. Subject of intr: prp-

3.1.2.2. VGCI of Ainu and Cham

1. Agent: A.: [prp-] * 7 prfx- ~ Ch.: prp- $(1/7 + 1)/2 \approx 0.57$
2. Causative: A.: -sfx ≠ Ch: prp₁-/prp₂- 0
3. Desiderative: A.: -pp ≠ Ch: prp- 0
4. Future simple: A.: -pp ≠ prp- 0
5. Imperative: A.: R/-pp ≠ Ch: -pp 0.75
6. Indiative: A: zero marker ~ Ch: zero marker 1
7. Iterative: A.: -RR-/sfx₁/-sfx₂/suppletivism ~ Ch: prfx-/pp: $(1/2 + 1/4)/2 \approx 0.37$
8. Interrogative: A.: -pp₁/-pp₂ ~ Ch.: -pp 0.75
9. Negation: A.: prp- ~ Ch.: prp₁-/prp₂-/crp---crp 0.66
10. Past simple: A.: -pp ~ Ch: prp₁-/prp₂-/-pp 0.66
11. Patient: A.: [prp-] * 7 prfx- ≠ Ch: -pp 0
12. Plural number: A.: [prp-] * 10 prfx-/prp-] * 2 -sfx/[prp-] * 10 prfx- * -sfx/prp- * -sfx * 2 -sfx/[prp-] * 10 prfx- * suppletivism/[prp-] * suppletion * 2 -sfx/[prp-] + 10 prfx- + -RR-/prp-] * -RR- * 2-sfx ~ Ch.: prp- $(1/48 + 1)/2 \approx 0.51$
13. Possibility ~ potential modality: A.: -pp ~ Chm.: -pp 1
14. Present continuous ~ Durative: A: -pp + -pp₁/-pp + -pp₂ ≠ Ch: prp₁/prp₂ 0
15. Present-future ~ general tense: zero marker ~ Ch: zero marker 1
16. Present perfect: A.: -pp ~ Ch: -pp₁/-pp₂/-pp₃ 0.66
17. Prohibitive: A.: prp- ~ Ch: prp- 1
18. Reciprocity: A.: prfx- ~ Ch.: prfx-/pp 0.75
19. Singular number: A.: [prp-] * 9 prfx-/prp-] 9prfx- * suppletiion ~ Ch: prp- $(1/18 + 1)/2 \approx 0.53$

20. Subject: A.: [prp-] * 5 prfx-/sfx₁/sfx₂ ~ Ch.: prp- $(1/7+1)/2 \approx 0.57$

VGCI (Ainu and Cham) is the following:

$$(20/40 + 20/28)/2 * (4 + 2*0.75 + 3*0.66 + 2*0.57 + 0.53 + 0.51 + 0.37)/20 \approx 0.32.$$

Such value of VGCI means that languages are unrelated.

Figure 3. The region where Cham language is located.

Figure 4. The map showing location of Cham speaking communities in Southern Vietnam.

3.1.3. Ainu and Hawaiian

The list of Ainu grammatical meanings can be seen in 3.1.1.1.

3.1.3.1. The List of Hawaiian Grammatical Meanings Expressed in the Verb and Their Positional Implementations

The list of Hawaiian grammatical meanings has been compiled after Krupa 1979.

1. Active voice: zero marker
2. Agent: -pp
3. Attemptive mood: prp-
4. Causative: prp-
5. Consequence: -pp
6. Deontic modality: prp-
7. Desiderative mood: prp-
8. Durative aspect: crp---crp₁/crp---crp₂
9. Frequency: -RR-
10. "If" mood: prp-
11. Imperative: prp-
12. Indicative mood: zero marker
13. Intensiveness: -RR-
14. Interrogative: -pp
15. Negation: prp-
16. Non-past tense ~ general tense: prp-
17. Passive voice: -pp
18. Past simple: prp-
19. Patient: -pp
20. Perfective aspect: prp-
21. Plural number: -RR- + -pp/prfx- + pp/-pp
22. Possibility: prp-
23. Prohibitive mood: prp-
24. Reason ~ in order to: prp-
25. Singular number: -pp
26. Subject: -pp

3.1.3.2. VGCI of Ainu and Hawaiian

1. Agent: A.: [prp-] * 7 prfx- ≠ H.: -pp 0
2. Causative: A : -sfx ≠ H.: prfx- 0
3. Deontic modality: A.: -pp ≠ H.: prp- 0
4. "If" mood ~ Subjunctive mood: A.: -pp ≠ H.: prp- 0
5. Imperative: A.: R/-pp ≠ H.: prp- 0
6. Indicative: A.: zero marker ~ H.: zero marker 1
7. Intensiveness: A.: -RR-/ -sfx₁/ -sfx₂/suppletion ~ H.: -RR- 0.62
8. Iterative ~ Frequency: A: -RR-/ -sfx₁/ -sfx₂/suppletion ~ H: -RR- 0.62
9. Interrogative: A.: -pp₁/ -pp₂ ~ H.: -pp 0.75
10. Negation.: A.: prp- ~ H.: prp- 1
11. Past simple tense: A.: -pp ≠ H.: prp- 0
12. Patient: A.: [prp-] *7 prfx- ≠ H.: -pp 0

13. Plural number: A.: [prp-] * 10 prfx-/ [prp-] * 2 -sfx/[prp-] * 10 prfx- * -sfx/prp- * -sfx * 2 -sfx/[prp-] * 10 prfx- * suppletion / [prp-] * suppletion * 2 -sfx/[prp-] * 10 prfx- * -RR-/ [prp-] * -RR- * 2-sfx ~ H.: -RR- + -pp/prfx- + pp/-pp (3/48 + 1)/2 $\approx$ 0.53
14. Possibility ~ potential modality: A.: -pp $\neq$ H.: prp- 0
15. Present continuous: A: -pp + -pp1/ -pp + -pp2 $\neq$ H: crp---crp₁/crp---crp₂ 0
16. Present-future (general tense) ~ Non-past tense: A.: zero marker ~ H.: prp- 0
17. Present perfect ~ perfective aspect: A.: -pp $\neq$ H.: prp- 0
18. Prohibitive: A.: prp- ~ H.: prp- 1
19. Reason/intention A.: -pp $\neq$ H.: prp- 0
20. Singular number: A.: [prp-] * 9 prfx-/ [prp-] * 9prfx- * suppletion $\neq$ H. -pp 0
21. Subject: A: [prp-] * 5 prfx-/ 2 -sfx ~ H: -pp (1/7 + 1)/2 $\approx$ 0.57

VGCI (Ainu; Hawaiian) is the following:

$$(21/26 + 21/40)/2 * (3 + 2*0.62 + 0.75 + 0.57 + 0.53)/21 \approx 0.19$$

Such value of VGCI means that compared languages are unrelated.

3.2. VGCI Proves that Ainu and Mon-Khmer are Unrelated

There is also a hypothesis that Ainu is a distant relative of Mon-Khmer (see, for instance: Vovin 1993). In order to see whether Ainu is a relative of Mon-Khmer VGCI is applied to Ainu and languages of Mon-Khmer stock.

3.2.1. *Ainu and Khmer*

The list of Ainu meanings can be seen in 3.1.1.1.

3.2.1.1. The List of Khmer Grammatical Meanings Expressed in the Verb and Their Positional Implementations

The list of Khmer grammatical meanings has been compiled after Gorgoniev 1961; Haiman 2011.

1. Active: zero marker
2. Agent: prp-
3. Causative1: prfx-/ -infx-
4. Causative2: prp-
5. Centrifuga1 version 1: -pp
6. Centrifugal version 2 “to go out” –pp
7. Centripetal version –pp
8. Deontic modality1: prp-
9. Deontic modality 2: prp-
10. Durative aspect: prp-
11. Future simple: prp-
12. General aspect: zero marker
13. “If” mood: prp-
14. Impossibility: -pp
15. Imperative: R

16. Indicative: zero marker
17. Interrogative: -pp
18. Negation: prp-/crfx-crfx
19. Passive: prp-
20. Patient: -pp
21. Perfect aspect: prp-
22. Possibility: prp-/pp
23. Prohibitive: prp-
24. Subject: prp-
25. Version “to move down” -pp
26. Version “to move inside” -pp
27. Version “to rise up” -pp
28. Volition: prp-

3.2.1.2. VGCI of Ainu and Khmer

1. Agent: A: [prp-] * 7 prfx- ~ Kh: prp- $(1/7 + 1)/2 \approx 0.57$
2. Causative: A: -sfx ≠ Kh: prp-/prfx-/infx- 0
3. Deontic modality: A: -pp ≠ Kh: prp₁/prp₂ 0
4. Desiderative ~ Volition: A: -pp ≠ Kh: prp- 0
5. Future simple: A: -pp + -pp ≠ Kh: prp- 0
6. “If” mood: A: -pp ≠ Kh: prp 0
7. Imperative: A: R/-pp ~ Kh: R 0.75
8. Impossibility: A: -pp ~ Kh: -pp 1
9. Indicative: A: zero marker ~ Kh: zero marker: 1
10. Interrogative: A: -pp₁/pp₂ ~ Kh -pp 0.75
11. Negation: A: prp ~ Kh: prp-/crfx---crfx 0.75
12. Patient: A: [prp-] * 7 prfx- ≠ Kh: -pp 0
13. Possibility: A: -pp ~ Kh: prp-/pp 0.75
14. Present continuous ~ Durative aspect: A: -pp + -pp₁/ -pp + -pp₂ ≠ Kh: prp- 0
15. Present-future ~ General aspect: zero marker ~ Kh: zero marker 1
16. Present perfect: A: -pp ≠ Kh: prp- 0
17. Prohibitive: A: prp- ~ Kh: prp-
18. Subject: A: [prp-] +5 prfx-/sfx₁/sfx₂ ~ Kh: prp $(1/7 + 1)/2 \approx 0.57$

VGCI of Ainu and Khmer is the following:

$$(18/40 + 18/28)/2 * (3 + 4*0.75 + 2*0.57)/18 \approx 0.21.$$

Such value of VGCI means that compared languages aren't related.

3.2.2. Ainu and Vietnamese

The list of Ainu grammatical meanings can be seen in 3.1.1.1.

3.2.2.1. The List of Vietnamese Grammatical Meanings Expressed in the Verb and Their Positional Implementations

The list of Vietnamese grammatical meanings compiled after Panfilov 1993.

1. Active voice: zero marker
2. Agent: prp-
3. Benefactive voice (positive meaning): prp-
4. Causative: prp-
5. Deontic modality: prp₁-/prp₂-
6. Desiderative: prp-
7. Durative aspect: prp-
8. Experiential aspect: prp-
9. Future simple: prp-
10. General tense ~ aspect: zero marker
11. Immediate future: prp-
12. Imperative: R/-pp/crp-crp₁/crp-crp₂/prp₁-/prp₂-
13. Indicative mood: zero marker
14. Negation: prp-
15. Passive voice (negative meaning): prp₁-/prp₂-
16. Past tense: prp₁-/prp₂-
17. Patient: -pp
18. Possibility: prp-/pp
19. Prohibitive: prp₁-/prp₂-/prp₃-
20. Perfect aspect: prp-/pp
21. Recent past: prp-
22. Subject of intransitive: prp-
23. Version 1 “to go” -pp
24. Version 2 “to come” -pp
25. Version 3 “to go up” -pp
26. Version 4 “to go out” -pp

3.2.2.2. VGCI of Ainu and Vietnamese

1. Agent: A: [prp-] * 7 prfx- ~ V: prp- $(1/7 + 1)/2 \approx 0.57$
2. Causative: A: -sfx ≠ V: prp 0
3. Deontic: A: -pp ≠ V: prp₁-/prp₂- 0
4. Desiderative: A: -pp ≠ V: prp- 0
5. Future simple: A: -pp + -pp ≠ V: prp- 0
6. Imperative: A: R/-pp ~ V: R/-pp/crp---crp₁/crp---crp₂/prp₁-/prp₂- $(1 + 2/6)/2 \approx 0.66$
7. Indicative mood: zero marker ~ V: zero marker 1
8. Negation: A: prp- ~ V: prp- 1
9. Past simple: A: -pp ≠ V: prp₁-/prp₂- 0
10. Patient: A: [prp-] + 7 prfx- ≠ V: -pp 0
11. Possibility: A: -pp ~ V: prp-/pp 0.75
12. Prohibitive: A: prp- ~ V: prp₁-/prp₂-/prp₃- 0.66

13. Present continuous ~ Durative aspect: A: -pp + -pp₁/ -pp + -pp₂ ≠ V: prp-
14. Present-future ~ General tense: A: zero marker ~ V: zero marker 1
15. Present perfect: A: -pp ~ V: prp-/ -pp 0.75
16. Subject: A: [prp-] * 5 prfx-/ 2 -sfx ~ V: prp-(1/7+1)/2 ≈ 0.57

VGCI of Ainu and Vietnamese is the following:

$$(16/26 + 16/40)/2 * (3 + 2*0.75 + 2*0.66 + 2*0.57)/16 \approx 0.22.$$

Such value of VGCI means that compared languages aren't related.

4. VGCI PROVES THAT AUSTRONESIAN AND MON-KHMER STOCKS ARE RELATED

During searches for Ainu language relatives has been discovered that Austronesian and Mon-Khmer stocks are relatives.

The Idea that Austronesian languages are distant relatives of Mon-Khmer stock was first spoken out by Wilhelm Schmidt (Schmidt 1906); later ideas of Schmidt were developed by Paul K. Benedict (Benedict 1976); Benedict also included Tai-Kadai and Hmong-Mien languages in this hypothetical Austric stock. This hypothesis like any other hypotheses of distant relationship had no firm proves until now, it was based mostly on comparison of randomly chosen lexemes. That's why now VGCI method is applied to it.

4.1. Austronesian and Khmer

4.1.1. Cham and Khmer

The list of Cham grammatical meanings can be seen in 3.1.2.1; that of Khmer can be seen in 3.2.1.1.

1. Active voice: Ch: zero marker ~ Kh: zero marker 1
2. Agent: Ch: prp- ~ Kh: prp 1
3. Centrifugal orientation/version: Ch: -pp ~ Kh: -pp 1
4. Centripetal orientation/version: Ch: -pp ~ Kh: -pp 1
5. Causative: Ch: prp₁-/prp₂- ~ Kh: prfx-/prp-/ -infx- (1+2/3)/2 ≈ 0.83
6. Desiderative mood ~ Volition: Chm: prp- ~ Kh: prp- 1
7. Durative aspect: Ch: prp₁-/prp₂- ~ prp- 0.75
8. Future simple: Ch: prp- ~ Kh: prp- 1
9. General tense ~ General aspect: Ch: zero marker ~ Kh: zero marker 1
10. Imperative: Ch: -pp ≠ Kh: R 0
11. Indicative: Ch: zero marker ~ Kh: zero marker 1
12. Interrogative: Ch: -pp ~ Kh: -pp 1
13. Negation: Ch: prp₁-/prp₂-/crp-crp ~ Kh: prp-/crfx-crfx (1+2/3)/2 ≈ 0.83
14. Passive: Ch: prp₁-/prp₂- ~ Kh: prp- 0.75

15. Patient: Ch: -pp ~ Kh: -pp 1
16. Perfect aspect: Ch: prp-₁/prp-₂/prp-₃ ~ Kh: prp- 0.66
17. Potential modality ~ Possibility: Ch: -pp ~ Kh: prp-/pp 0.75
18. Subject: Ch: prp- ~ Kh: prp- 1

VGCI of Cham and Khmer is the following:

$$(18/28 + 18/28)/2 * 15.57/18 \approx 0.55.$$

Such value of VGCI (see 2.6). means that Cham and Khmer are rather close relatives.

Cham and Khmer have been usually supposed to be members of the same sprachbund, i.e., scholars thought Cham can look alike Khmer and alike other languages of the region due to local contact influence. Of course, contacts can influence, for instance, on degree of analytism/synthetism, but I seriously doubt that contacts can influence on fundamental levels of grammar, i.e., on positional distributions. However, let's test more.

4.1.2. *Hawaiian and Khmer*

The list of Hawaiian grammatical meanings can be seen in 3.1.3.1; that of Khmer can be seen in 3.2.1.1.

1. Active: H: zero marker ~ Kh: zero marker 1
2. Agent: H: -pp ≠ Kh: prp- 0
3. Causative: H: prfx- ~ Kh: prfx-/infx-/prp- 0.66
4. Deontic modality: H: prp- ~ Kh: prp₁/prp₂- 0.75
5. Desiderative mood ~ Volition: H: prp- Kh: ~ prp 1
6. Continuous ~ Durative: H: crp---crp₁/crp---crp₂ ≠ Kh: prp- 0
7. Non-past tense/aspect ~ General aspect: H: prp- ≠ Kh: zero marker 0
8. Imperative: H: prp- ≠ Kh: R 0
9. Indicative: H: zero marker ~ Kh: zero marker 1
10. "If" mood: H: prp- ~ Kh: prp- 1
11. Interrogative: H: -pp ~ Kh: -pp 1
12. Negation: H: prp- ~ Kh: prp-/crfx---crfx 0.75
13. Passive: H: -sfx ≠ Kh: prp- 0
14. Patient: H: -pp ~ Kh: -pp 1
15. Perfective aspect: H: prp- ~ Kh: prp-1
16. Possibility: H: prp- ~ Kh: prp-/pp 0.75
17. Prohibitive: H: prp- ~ Kh: prp 1
18. Subject: H: -pp ≠ Kh: prp- 0

VGCI of Hawaiian and Khmer is the following:

$$(18/26 + 18/28)/2 * (8 + 3 * 0.75 + 0.66)/18 \approx 0.39$$

Such value of VGCI means that languages are distant relatives.

4.1.3. Lha'alua and Khmer

The list of Lha'alua grammatical meanings can be seen in 3.1.1.2; that of Khmer can be seen in 3.2.1.1.

1. Actor voice ~ Active voice: K: zero marker ~ Lh: pf-/infx-/zero marker 0.66
2. Agent: K: prp- ≠ Lh: sfx 0
3. Causative: K: prp-/prfx-/infx- ~ Lh: prp- 0.66
4. Durative aspect: K: prp- ~ Lh: -RR- 1
5. Realis ~ General aspect: K: zero marker ~ Lh: zero marker 1
6. Future simple: ~ Irrealis: K: prp- ~ Lh: prfx-/infx-/RR- 0.66
7. Imperative: K: R ≠ Lh: -sfx 0
8. Indicative: K: zero marker ~ Lh: zero marker 1
9. Interrogative: K: -pp ~ Lh: -sfx 1
10. Locative voice ~ one of versions K: -pp₁/-pp₂/-pp₃/-pp₄/-pp₅/-pp₆ ~ Lh: -pp (1 + 1/6)/2 = 0.58
11. Negation: Kh: prp-/crfx---crfx ~ Lh: prp- 0.75
12. Passive voice ~ Patient voice: K: prp- ≠ Lh: -sfx 0
13. Perfective aspect: K: prp ~ Lh: prfx- 1
14. Possible modality: Kh: prp-/pp ~ Lh: -sfx 0.75
15. Progressive aspect: K: prp- ~ Lh: -RR- 1
16. Prohibitive: K: prp- ~ Lh: prp- 1

VGCI of La'alua and Khmer is the following:

$$(16/28 + 16/31)/2 * (7 + 2 * 0.75 + 3 * 0.66 + 0.58)/16 \approx 0.38.$$

Such value of VGCI means that languages are distant relatives.

4.2. Austroneisan and Vietnamese

4.2.1. Vietnamese and Cham

The list of Vietnamese meanings can be seen in 3.2.2.1; that of Cham can be seen in 3.1.2.1.

1. Active voice: V: zero marker ~ Ch: zero marker 1
2. Agent: V: prp- ~ Ch: prp- 1
3. Causative: V: prp- ~ Ch: prp₁/prp₂- 0.75
4. Centrifugal orientation ~ Version 4 "to go out": V: -pp ~ Ch: -pp 1
5. Centripetal orientation ~ to come: V: -pp ~ Ch: -pp 1
6. Desiderative mood: V: prp- ~ Ch: prp- 1
7. Durative aspect: V: prp- ~ Ch: prp₁/prp₂- 0.75
8. Future: V: prp- ~ Ch: prp- 1
9. General tense: V: zero marker ~ V: zero marker 1
10. Imperative: V: R/-pp/crp-crp₁/crp-crp₂/prp₁/prp₂- ~ Chm: -pp 0.58
11. Indicative: V: zero marker ~ Ch: zero marker 1
12. Negation: V: prp- ~ Ch: prp₁/prp₂-crp-crp 0.66

13. Passive voice: V: prp₁-/prp₂- ~ Ch: prp₁-/prp₂- 1
14. Past tense: V: prp₁-/prp₂- ~ Ch: prp₁-/prp₂-pp 0.83
15. Patient: V: -pp ~ Chm: -pp1
16. Perfect: V: prp-/pp ~ Ch: prp₁-/prp₂-prp₃ 0.41
17. Possibility: V: prp-/pp ~ Ch: -pp 0.75
18. Prohibitive: V: prp₁-/prp₂-prp₃ ~ Ch: prp- 0.66
19. Subject: V: prp- ~ Ch: prp- 1

VGCI of Vietnamese and Cham is the following:

$$(19/26 + 19/28)/2 * (11 + 0.83 + 3 * 0.75 + 2 * 0.66 + 0.58 + 0.41)/19 \approx 0.6.$$

Such value of VGCI means that compared languages belong to the same stock.

4.2.2. Vietnamese and Hawaiian

The list of Vietnamese meanings can be seen in 3.2.2.1; that of Hawaiian can be seen in 3.1.3.1.

1. Active voice: V: zero marker- ~ H: zero marker 1
2. Agent: V: prp- ~ H: -pp 0
3. Causative: V: prp- ~ H: prfx- 1
4. Deontic modality: V: prp₁-/prp₂- ~ H: prp 0.75
5. Desiderative mood: V: prp- ~ H: prp- 1
6. Durative aspect: prp- ≠ crp-crp₁/crp-crp₂ 0
7. Imperative: V: R/-pp/crp-crp₁/crp-crp₂/prp₁-/prp₂- ~ H: prp- 0.58
8. Indicative: V: zero marker ~ H: zero marker 1
9. Negation: V: prp- ~ H: prp- 1
10. Non-past tense: V: zero marker ≠ H: prp- 0
11. Passive voice: V: prp₁-/prp₂- ≠ H: -sfx 0
12. Past tense: V: prp₁-/prp₂- ~ H: prp- 0.75
13. Patient: V: -pp ~ H: -pp 1
14. Perfect aspect: V: prp-/pp ~ H: prp- 0.75
15. Possibility: V: prp-/pp ~ H: prp- 0.75
16. Prohibitive: V: prp₁-/prp₂-prp₃- ~ H: prp- 0.66
17. Subject: V: prp- ≠ H: -pp 0

VGCI of Vietnamese and Hawaiian is the following:

$$(17/26 + 17/26)/2 * (6 + 4 * 0.75 + 0.66 + 0.58)/17 \approx 0.39.$$

Such value of VGCI means that compared languages are distant relatives.

4.2.3. Vietnamese and Lha'alua

The list of Vietnamese meanings can be seen in 3.2.2.1; that of Lha'alua can be seen in 3.1.1.2

1. Active voice ~ Actor voice: V: zero marker ~ Lh: pf-/infx-/zero marker + R 0.66
2. Agent: V: prp- ≠ V: -sfx 0

3. Causative: V: prp- ~ Lh prp- 1
4. Durative aspect: V: prp- ~ Lh: -RR- 1
5. Experience ~ Experiential: V: prp- ~ Lh: prp- 1
6. General tense ~ realis: V: zero marker ~ Lh: zero marker 1
7. Future ~ irrealis: V: prp- ~ Lh: prfx-/infx-/RR- 0.66
8. Imperative: V: R/-pp/crp-crp₁/crp-crp₂/prp₁-prp₂- ~ Lh: sfx (1 +1/6)/2 = 0.58
9. Indicative: V: zero marker ~ Lh: zero marker 1
10. Irrealis ~ future: V: prp- ~ Lh: prfx-/infx-/RR- 0.66
11. Locative voice ~ any version: V: -pp₁/pp₂/pp₃/pp₄ ~ Lh: -sfx₁/sfx₂/sfx₃ 0.87
12. Negation: V: prp- ~ Lh: prp- 1
13. Passive voice ~ patient voice: V: prp₁-prp₂- ≠ Lh: -sfx 0
14. Perfect aspect: V: prp-/pp ~ Lh: prfx- 0.75
15. Possibility: V: prp-/pp ~ Lh: sfx 0.75
16. Prohibitive: V: prp₁/prp₂/prp₃ ~ Lh: prp- 0.66

VGCI of Vietnamese and Lha'alua is the following:

$(16/26 + 16/31)/2 * (6.87 + 2.64 + 1.5 + 0.58)/16 \approx 0.4$.

Such value of VGCI means that languages belong to the same stock.

4.3. Conclusion about Austronesian and Mon-Khmer Stocks Relatedness

4.3.1. General Notes on Proximity of Grammatical Meanings Distributions

Values of VGCI received above evidently show relatedness of Austronesian and Mon-Khmer (Austroasiatic)¹² stocks:

VGCI of Khmer and Cham is 0.55;

VGCI of Khmer and Hawaiian is 0.39;

VGCI of Khmer and Lha'alua is 0.38.

VGCI of Vietnamese and Cham is 0.6;

VGCI of Vietnamese and Hawaiian is 0.39;

VGCI of Vietnamese and Lha'alua is 0.4

These data should be interpreted in the context of VGCI values of languages of firmly assembled stocks:

VGCI of English and Russian is 0.52;

VGCI of English and Lithuanian is 0.43;

VGCI of English and Latin is 0.41;

VGCI English and Persian is 0.38;

VGCI of Hawaiian and Lha'alua is 0.39;

VGCI of Chinese and Tibetan is 0.39.

¹² As far as Mon-Khmer is just a part of Austroasiatic stock, so due to transitivity of relatedness it's possible to state relatedness of whole Austronesian to whole Austroasiatic. And thus it is possible to name this Austronesian-Mon-Khmer stock Austric stock.

Probably in the case of Cham and Khmer and in the case of Cham and Vietnamese it is possible to speak about certain contact influence. In the case of Cham and Vietnamese value of VGCI actually shows that they belong not even to the same stock, but to the same group (VGCI value of a group should be higher than 0.56, for more details see Akulov 2016). I don't think that contact influence can seriously change deep levels of grammar, i.e., basic positional distributions of grammatical meanings; contacts usually influence on superficial items of languages, for instance: language can become less or more analytical, can appear certain new affixes, but no contacts can influence can't fundamental level of grammar. And I want to ask those who are obsessed by the mythology of "languages in contacts": what "contact influence" was in the case of Khmer and Hawaiian or in the case of Hawaiian and Vietnamese?

4.3.2. Some Characteristic Features of So Called Austric Stock

4.3.2.1. Markers of Causative

Beside above shown general proximity/similarity of positional distributions of common grammar meanings there are certain noteworthy grammatical similarities.

One of such similarities is the way of expression of causative mood/causative voice in Austroneisan and Mon-Khmer: in both stocks causative is expressed by prepositions/prefixes; in Austronesian languages can be seen even an amazing material resemblance of causative markers: Cham: *pa-*; Hawaiian: *ho'o-/hō* " *-hō-/ha'a-/hā* " *-hā-*; La'alua: *poa-*. In Khmer can be seen almost the same prefix: *p-* (taking into consideration the fact that degree of consonantism of Khmer seems to be higher than that of Cham, so it's rather possible to suppose drift from *pa-* in Cham to *p-* in Khmer). In Vietnamese we don't see such form (probably if we pay attention to certain dialects we can see something alike) and causative is expressed by a newly made form, but anyway this newly made form is prefixed/preposed.

4.3.2.2. The System of Focus/Triggers/Orientations

Another amazing structural similarity is so called focuses/triggers system, i.e., system of several voices; each voice accents on certain particular issue of action/process: on agent, on instruments, on location, on patient et c. Due to this fact such system of voices is called the system of focuses.

Austronesian languages (especially Austronesian languages of Taiwan) are well known for their systems of focuses; while in Mon-Khmer languages systems of focuses are almost unknown. However, in Vietnamese we actually can see focuses system: it is possible to say that in Vietnamese there are focuses: actor focus, benefactive focus and patient focus; this system correlates well with Austronesian system that is well represented in Lha'alua.

I hardly can imagine that system of focuses is a new item appeared in Vietnamese due to contacts with languages of Austronesian. I would rather suppose gradual decay of system of focuses in Vietnamese under the influence of contacts and appearing a Chinese alike system of two voices; however, as I mentioned above I think that contacts influence actually is too much overrated.

The only possible conclusion is that such system of focuses in Vietnamese obviously is a relic of a well elaborated focuses system of Formosan/Philippine type.

In Cham and in Khmer, however, we don't see focuses, but in Cham and in Khmer we can see orientations.

Orientation (or spatial orientation) is a special grammatical category that is used when speaker/subject attitude toward an action/process is expressed by, for instance, verbs of movement.

Orientations can be seen in different languages, for instance: in Ket there are spatial orientation markers (Werner 1997: 183); in Japanese there are directionally tinted aspectual markers (Lavrent'yev 2002: 127 – 133) and markers of whether an action/process is focused on subject or patient – these last are actually connected with Japanese system of formalized politeness (Ibid: 174 – 181).

Whether the system of orientations in Ket or in Japanese was somehow connected with any system of focuses is theme for special research; however, I do suppose that in the case of Austronesian and Mon-Khmer it is possible to speak about transformation of focuses system into the system of orientations/versions.

In Vietnamese there are three triggers and four orientations: *ra* “to go out”, *lên* “to ascend”, *lại* “to come”, *đi* “to go” (Panfilov 1993: 182 – 183).

In Khmer we don't see triggers, but we can see just a system of orientations: *cen* “to go out”, *mōk* – centripetal, *coh* – “to move down”, *cōl* “to enter”/“to move inside” inside”, *laən* “to ascend” (Gorgoniev 1961: 94 – 95).

In Cham we can see only two markers or orientation: *ngw* “to go” – centrifugal orientation and *maj* “to come” – centripetal orientation (Alieva, Bui 1999: 73).

Thus, as I suppose, it is possible to conclude the following:

Austronesian has triggers system, in Vietnamese we can see relics of triggers and well elaborated system of orientations; in Khmer and Cham we don't see triggers but see systems of orientations, so I came to the conclusion that in the case of Austric languages triggers system could transform into the system of orientations (spatial orientations are especially well correlated with locative triggers). Anyway this is theme for further reasearches.

4.3.2.3. Further Perspectives of Austric Stock

After Austronesian and Mon-Khmer relationship has been firmly proved then, first of all, should be solved the following questions: whether Tai-Kadai and Hmong-Mien stocks are relatives of Austric stock.

Also I am specially to note that typological proves don't deny discovering of cognates, though many megalocomparativists probably think it does.

Of course, typology is the base, but since typological relatedness has been firmly proven there is no obstacles for discovering cognates that obviously exist, but cognates should be true cognates.

5. VGCI PROVES THAT AINU IS RELATIVE OF GREAT ANDAMANESE AND SINO-TIBETAN STOCKS

5.1. VGCI Proves that Ainu Is a Relative of Great Andamanese

5.1.1. General Notes on Great Andamanese and Other Languages of Andaman Islands

The Great Andamanese languages are an extinct stock¹³ spoken by the Great Andamanese peoples of the Andaman Islands¹⁴, in the Indian Ocean.

Great Andamanese stock is supposed to be unrelated to other languages spoken upon the island of Andaman: such as Ongan (Jangil, Jarawa and Onge) and to Sentinelese¹⁵ (Abbi 2009). However, I suppose that actually Great Andamanese and Ongan stocks probably can be distant relatives.

5.1.2. The List of Great Andamanese Grammatical Meanings Expressed in the Verb and Their Positional Implementations

The list of Great Andamanese meanings has been compiled after Choudary 2006.

1. Agent: [prp-] * 8 prfx-
2. Causative: prfx-
3. Conditional: -sfx
4. Durative: -sfx
5. *Evidentiality¹⁶ 1 “hearsay”
6. *Evidentiality 2 “it can be seen”
7. Exclusive: prfx-1/prx-2/prx-3
8. Habitual: -sfx
9. Imperative: -sfx
10. Inclusive: prfx-1/prx-2
11. Indicative: -sfx
12. Interrogative: prp-
13. Negation prfx-/-sfx
14. Non-past: -sfx
15. Past simple: -sfx
16. Patient: prfx-1/prfx-2/prfx-3/prfx-4/prfx-5
17. Plural number: [prp-] + prfx-
18. Prohibitive: -sfx
19. Reason: -pp
20. Reflexivity: prfx-

¹³ Despite Great Andamanese is actually a stock, but in current text they are considered as a single language.

¹⁴ Figure 5.

¹⁵ Sentinelese language hasn't been described anyhow yet since Sentinelese people intentionally escape any contacts with anthropologists/linguistics (Lukina 2016).

¹⁶ The description of Great Andamanese that I used is actually rather meager, it seems that some features of verb aren't mentioned, that's why I suppose it's possible to reconstruct some features, i.e.: it's possible to reconstruct such features as markers of evidentiality since they obviously should be represented in this language.

21. Singular number: [prp-] * 4 prfx-
22. Subject: [prp-] * 8 prfx-
23. Transitivity: prfx-

5.1.3. VGCI of Ainu and Great Andamanese

The list of Ainu grammatical meanings with their positional distributions can be seen in 3.1.1.1.

1. Agent: A: [prp-] * 7 prfx- ~ An.: [prp-] * 8 prfx- $(1 + 7/8)/2 \approx 0.94$
2. Causative: A: -sfx $\neq$ An: prfx- 0
3. Conditional ~ Future conditional: A: -pp₁/-pp₂ ~ An: -pp 0.75
4. Durative: A: -pp + -pp₁/-pp + -pp₂ ~ An: -sfx 0
5. Evidentiality “hearsay”: A: -pp ~ An: -pp 1
6. Evidentiality “it can be seen”: A: -pp ~ An: -pp 1
7. Exclusive: A: prfx₋₁/prfx₋₂/-sfx ~ An: prfx₋₁/prx₋₂/prx₋₃ 0.66
8. General tense ~ Non-past: A: zero marker $\neq$ An: -sfx 0
9. Inclusive: A: prfx₋₁/prfx₋₂/-sfx ~ An: prfx₋₁/prfx₋₂ $(1 + 2/3)/2 \approx 0.83$
10. Imperative: A: R/-pp $\neq$ An: -sfx 0.75
11. Indicative: A: zero marker ~ An: -sfx 0
12. Interrogative: A: -pp₁/-pp₂ $\neq$ An: prp- 0
13. Negation: A: prp ~ An: prfx-/sfx 0.75
14. Plural number: A: [prp-] * 10 prfx-/ [prp-] * 2 -sfx/[prp-] * 10 prfx- * -sfx/[prp-] * -sfx * 2 -sfx/[prp-] * 10 prfx- * suppletion/[prp-] * suppletion * 2 -sfx/[prp-] * 10 prfx- * -RR-/ [prp-] * -RR- * 2-sfx ~ An.: 6 prfx- $(1 + 6/8)/2 \approx 0.56$
15. Past simple: A: -pp ~ An: -sfx 1
16. Patient: A: 7 prfx- ~ 5 prfx- $(1 + 5/7)/2 \approx 0.86$
17. Prohibitive: Ai: prp- $\neq$ An: -sfx 0
18. Reason: A: -pp ~ An: -pp 1
19. Reflexivity: A: prfx- ~ An: prx- 1
20. Singular number: Ai: [prp-] * 9 prfx-/ [prp-] * 9prfx- * suppletion ~ An.: 4 prfx- $(1 + 4/18)/2 \approx 0.61$
21. Subject: A: [prp-] * 5 prfx-/ [prp-] * 2 -sfx ~ 8 prfx- $(5/7 + 5/8)/2 \approx 0.66$
22. Transitivity: Ai: prfx- ~ An: prfx- 1

VGCI Ainu and Great Andamanese is the following:

$$(22/24 + 22/40)/2 * (5 + 0.94 + 3*0.75 + 2*0.66 + 0.83 + 0.86 + 0.56 + 0.61)/22 \approx 0.4.$$

Such value of VGCI is the same as value of VGCI of English and Persian (see 2.6).

Figure 5. Spread of Great Andamanese and other languages of the Andaman islands in the beginning of 19th century (Source: Abbi, A. The Unique Structure...).

5.2. VGCI Proves that Ainu and Sino-Tibetan Stock Are Relatives

5.2.1. The List of Qiang Grammatical Meanings Expressed in the Verb and Their Positional Implementations

The list of Qiang meanings has been compiled after LaPolla, Huang 1996. Geographic location of Qiang language can be seen in pic 6.

1. Actor: 6 -sfx
2. Ability 1 learned: -sfx
3. Ability 2 natural: -sfx₁/-sfx₂
4. Ability 3: -sfx
5. Causative: -sfx

20. Hortative: -pp₁/-pp₂/-pp₃/-pp₄
21. Imperative: zero marker
22. Imperfective aspect: zero marker
23. Indicative: zero marker
24. Intentional: -sfx + -pp
25. Interrogative: -pp₁/-pp₂/-pp₃/-pp₄/-pp₅
26. Negation: prfx-
27. Optative: -pp₁/-pp₂/-pp₃
28. Patient/non-actor/benefactive: 6 -sfx
29. Perfective aspect – resultative: 8 prfx-/prfx- + -pp
30. Permissive: -sfx
31. Plural: 9 -sfx
32. Prohibitive: prfx-/pp₁/-pp₂
33. Reciprocity: -RR-
34. Repetition: -sfx
35. Resultative: prfx- + -pp
36. Simultaneity: -pp
37. Singular: 9 -sfx
38. Subject: 6 -sfx

5.2.2. VGCI of Ainu and Qiang

The list of Ainu meanings can be seen in 3.1.1.1.

1. Actor: A: [prp-] * 7 prfx- $\neq$ Q: 6 -sfx 0
2. Causative: A: -sfx $\sim$ Q: -sfx 1
3. Deontic: A: -pp $\sim$ Q: -sfx + -pp 1
4. Desiderative: A: -pp $\sim$ Q -sfx 1
5. Durative $\sim$ Continuative: A: -pp + -pp₁/ -pp + -pp₂ $\sim$ Q: prfx-/sfx 0.5
6. Evidentiality “people say” $\sim$ hearsay: A: -pp $\sim$ Q -sfx 1
7. Evidentiality: “speaker has seen it” $\sim$ see: A: -pp $\sim$ Q: -sfx 1
8. Experiential aspect $\sim$ Past simple: A: -pp $\sim$ Q -sfx 1
9. Hortative: A: -pp $\sim$ Q: -pp₁/-pp₂/-pp₃/-pp₄ $(1 + \frac{1}{4})/2 = 0.625$
10. Imperative: A: zero marker/-pp $\sim$ Q: zero marker 0.75
11. Imperfective $\sim$ General tense: A: zero marker $\sim$ Q zero marker 1
12. Indicative: A: zero marker $\sim$ Q: zero marker 1
13. Intention: A: -pp $\sim$ Q -sfx + pp 1
14. Interrogative: A: -pp₁/-pp₂ $\sim$ Q: -pp₁/-pp₂/-pp₃/-pp₄/-pp₅ $(1 + 2/5)/2 = 0.7$
15. Negation: A: prp- $\sim$ Q: prp- 1
16. Patient: A: [prp-] * 7 prefixes $\neq$ Q: 6 -sfx 0
17. Perfective aspect: A: -pp $\neq$ Q: 8 prfx-/prfx- + -pp 0
18. Plural: A: [prp-] * 10 prfx-/ [prp-] * 2 -sfx/[prp-] * 10 prfx- * -sfx/prp- * -sfx * 2 -sfx/[prp-] * 10 prfx- * suppletion/[prp-] * suppletion * 2 -sfx/[prp-] * 10 prfx- * -RR-/ [prp-] * -RR- * 2-sfx $\sim$ Q: 9 -sfx $(6/48 + 6/9)/2 = 0.39$
19. Potential: A: -pp $\sim$ Q: -pp₁/-pp₂/-pp₃/-pp₄ $(1 + \frac{1}{4})/2 = 0.625$
20. Prohibitive: A: prp- $\sim$ Q: prfx-/ -pp₁/-pp₂ $(1+1/3)/2 = 0.66$
21. Reciprocity: A: prfx- $\neq$ Q: -RR¹⁷- 1
22. Repetition: A: -RR-/suppletion/-sfx₁/-sfx₂ $\sim$ Q: -sfx $(1 + \frac{1}{4})/2 = 0.625$
23. Singular: [prp-] * 9 prfx-/ [prp-] * 9prfx- * suppletion $\neq$ Q: 9 -sfx 0
24. Subject: A: [prp-]+ 5 prfx- / 2-sfx $\sim$ Q: 9 -sfx $(2/7+2/9)/2 = 0.25$

VGCI of Ainu and Qiang is the following:

$$(24/38 + 24/40)/2*(11 + 0.5 + 0.75 + 0.7 + 3*0.625 + 0.39 + 0.66 + 0.25)/24 \approx 0.4;$$

It means that Ainu and Qiang are relatives.

Thus, due to transitivity of relatedness, it is possible to state that Ainu is a relative of whole Sino-Tibetan stock.

5.3. Particular Conclusion about Ainu-Andamanese-Sino-Tibetan Stock

5.3.1. Ainu-Andamanese-Sino-Tibetan Stock

Now it is possible to speak about Ainu-Andamanese-Sino-Tibetan stock.

¹⁷ It is possible to say that reduplication can be interpreted as prefixation.

Main structural features of the stock are the following: voices are badly elaborated; often can be seen personal markers; also category of evidence is elaborated rather well.

Qiang is closer to Ainu than to Mandarin.

Mandarin language is a marginal idiom inside the stock since it has well elaborated category of voice and has no category of evidence.

It seems that Mandarin underwent certain influence of Austric languages since Austric languages have a well elaborated category of voice (system of trigger/focuses, see 4.3.2.2).

Figure 6. Geographic spread of Ainu-Andamanese-Sino-Tibetan stock; genetic evidences and perspective territories for looking for other relatives of the stock.

5.3.2. *Evidences of Genetics*

Cultures and languages are usually considered separately from the data of genetics, and often can be seen the opinion that cultural anthropology should not use data of genetics. However, I have to note that since languages and cultures are spread not by themselves, but by people so influence of certain culture has to correlate with corresponding genetic traces (Nonno 2016a: 46).

Different subclades of Y haplogroup D-M174 are rather widely spread among people of Southwest China (Xue et al. 2006). The same Y haplogroup can be seen among Ainu people (Tajima et al. 2004) and among Andamanese (Chandrasekar et al. 2007).

It's notable fact that nowadays geographic spreading of languages preserving old features of Ainu-Andamanese-Sino-Tibetan stock correlates with that of Y haplogroup D (Figure 6).

It seems that initially large spaces of Southern and East Asia were occupied by people with Y haplogroup D and they were the first speaker of the idiom that was proto-language of Ainu-Andamanese-Sino-Tibetan stock.

As it has been noted in 5.3.1 it seems that initially Mandarin also was a language with a set of typical features of the stock, but had been undergone serious influence of certain Austric languages; and this hypothesis also correlate well with data of genetics, since there is almost no Y haplogroup D in the plains of China. It seems that people of Y haplogroup D mixed with newcomers who spoke Austric languages and bore Y haplogroup O upon the plains, or were ousted to the mountain where they could save their languages.

5.3.3. *Evidences of Culture*

Ornaments of Ainu textile and those of Shang bronzes demonstrate noteworthy resemblance. Basic element of both ornamental traditions is so called rectangular volute (Nonno 2016b: 54).

5.3.4. *Location of Proto-Language of Ainu-Andamanese-Sino-Tibetan Stock*

Proto-language of Ainu-Andamanese-Sino-Tibetan stock probably located somewhere in South Asia.

5.3.5. *Other Potential Relatives*

Potential relatives can probably be found among West Papuan and Halmahera languages (Figure 5).

Another potential relative is Ongan family. Despite Ongan languages are usually considered as unrelated to Great Andamanese (Abbi 2009), but it seems rather possible that they can be distant relatives.

Also, certain lexical relics can probably be found in languages of so called Orang Asli and Aeta. Despite now they are Austronesian speaking ethnic groups, in their languages there are some words of non-Austronesian origin (Reid 1994).

5.3.6. *On the Origin of Ainu*

Above described facts are firm evidences of southern origin of Ainu. Ainu people seem to be relic of a very large population that was spread throughout South and Southeast Asia in a very distant past.

CONCLUSION ABOUT VGCI METHOD

The basic idea of VGCI method is very simple:

Grammar is first of all positional distributions of grammatical means, i.e., ordered pair of the following view: $\langle A; \Omega \rangle$ where A is set of grammatical meanings and Ω is set of operations (positional distributions) defined on A .

In order to understand whether two languages are genetically related we should analyze the degree of correlation of grammatical meanings sets and to estimate the proximity of positional distributions of common grammatical meanings.

If value of VGCI is about 0.4 or more than 0.4 then languages are related (i.e., belong to the same stock), if value of VGCI is about 0.3 or less than 0.3 then languages are not related. Such values as 0.39 and 0.38 also are variants of 0.4; while 0.31 or 0.32 are variants of 0.3. The more closely are certain languages related, the higher is value of corresponding VGCI.

The more precise is notation the more precise will be conclusions. Current way of notation allows seeing whether languages are related, but obviously it can become more precise.

Good grammars and correct notation are matters of utmost importance in VGCI method. It's better not to estimate VGCI at all rather than estimate it inaccurately. I mean the following: if someone receives VGCI value, for instance: 0.35, it means that there are some serious mistakes in notation or it simply means that grammar simply doesn't describe a language in a sufficient way.

There can be no languages demonstrating such odd values as 0.35; VGCI of any pair of languages is somewhere outside of this "corridor of death" between 0.3 and 0.4.

Actually VGCI allows some backlash, since, as it has been shown, very different descriptions give almost the same values, but VGCI obviously doesn't allow omission of the milestones of grammars.

Set of contentive grammatical meanings of any language is actually rather small: it hardly can count more than 50 elements and hardly can count less than 20. If certain list of grammatical meanings consists of less than 20 elements, then it should cause doubts about the correctness of a particular notation.

Differentiation between syntax and morphology has no real base: it can be especially clearly seen on the material of Austronesian stock: among Austronesian languages there are languages that "look alike" Vietnamese and Khmer (for instance Cham), i.e., from "traditional" point of view have no morphology; there are languages that "look alike" Ainu (for instance Lha'alua), i.e., have well elaborated morphology; and there languages that probably from that "traditional point of view" look alike "Austronesian itself" (for instance Hawaiian); and all these languages that are "so much different typologically" show rather similar positional distributions of grammatical categories. It also means that typology should be not collecting of curiosities, but should be study of positional distributions of all grammatical categories of verb represented in a certain language.

An important consequence from the previous point is the principle that can be conventionally named principle of grammar distribution stability, i.e., degree of synthetism/analytism can changes, morphology can convert itself into syntax or vice versa, but positional distributions of most important grammatical categories remain the same.

Unrelatedness of languages can be proved; anyone who states that it's impossible just steps outside of basic logic and outside of science.

VGCI can be extremely perspective in Americas, New-Guinea and Australia, i.e., in those areas where exist many languages which genetic affiliation is doubtful or simply unknown.

Chapter 17

**ACADEMIC LITERACY ADAPTATION IN THE
INTERNATIONAL GRADUATE STUDENTS’
USE OF LEXICAL BUNDLES THROUGH
CORPUS RESEARCH**

Eunjeong Park*

The Ohio State University, Columbus, Ohio, US

ABSTRACT

More and more international students come to the United States to study in higher education. Due to the increasing number of the population, international students are considered crucial for the economic and social impact on academia in the U.S. For instance, they have contributed more than 30.8 billion dollars to the economic vigor of the U.S. higher institutions and their communities. However, international students’ adaptation may not be successful due to several reasons. One of them would be their language proficiency—in particular, productive language skills: writing and speaking. In the academic setting, many international students struggle with their written assignments in English. Acknowledging the international students’ challenge of academic writing in English, this study investigated international graduate students’ academic literacy adaptation via corpus research. The use of lexical bundles was examined as one of the academic literacy adaptation indicators in this corpus-based study. The results revealed that the students did not use stance lexical bundles, indicating that they may not express their own voices in critical reviews. Rather, they tend to write carefully to reflect the original articles. This study suggests that we should view international students’ academic literacy adaptation with larger corpus data. Further implications of the findings are discussed.

1. INTRODUCTION

Prior research (e.g., Cheng & Fox, 2008; Spack, 1997) shows that a lot of international students face challenges in their adaptation process while studying in a foreign country. More and more international students come to the United States to study in higher education. According to *Open Doors 2016*, the number of international students studying in the United States grew by 7.1% over the prior year in 2015-2016 and was at a record high; international students constituted approximately 5.2% enrolled in the total U.S. higher education student population in the year 2015-2016 (“Institute of International Education,” 2016). The increasing population of international students has brought social and economic influence on higher education in the U.S. Their contribution to the U.S. higher education also includes providing a wide range of viewpoints in the U.S. classrooms.

In spite of the benefits that international students bring to higher educational contexts, the academic adaptation may not be reached to their expectation. For example, Park’s (2016) study showed that the participating international graduate students perceived that their sociocultural adaptation was agreeable with 93 percent of positive responses. The international graduate students seemed socially and culturally adjusted well to the target culture and society. However, the dimensions of academic adaptation and academic literacy adaptation yielded lower percentages (77.88% & 68.17% respectively). This indicates that international students have difficulty in academic adaptation and especially the adaptation of second language writing. Realizing international students’ challenge of academic writing in English, this study investigated international graduate students’ academic literacy adaptation via corpus research. In particular, this study focused on the international students’ lexical bundle use. To better understand the nature of their language use and assist them to improve their English language skills, it is necessary to examine how international students receive the input and yield the output via second language writing. In this sense, lexical bundles can manifest the extent of academic literacy adaptation. Thus, this study poses the following research questions:

1. What structural characteristic of lexical bundles are included in the participants’ second language writing?
2. What functional characteristics of lexical bundles are included in the participants’ second language writing?
3. Which features of lexical bundles used by the participants show academic literacy adaptation in second language writing?

2. LITERATURE REVIEW

2.1. Academic Adaptation through Second Language (L2) Writing

A growing body of literature of academic adaptation of international students, whose first language is not English, in higher education has focused on second language learners’ processes of engagement in the university settings (e.g., Cheng & Fox, 2008; Ivanič, 2006; Leki, 1995, 2007; Morita, 2000; Spack, 1997). Spack’s (1997) longitudinal case study

explored one international undergraduate student's reading and writing strategies in the U.S. academic context. The study analyzed multiple data sources, including interviews, observations, and texts from the participant's courses, and examined the linguistic, cultural, and educational factors of the participant's learning in a second language. The results revealed an inseparability of reading and writing processes and the participant's strategy of applying previous literacy skills to new course materials. Spack's (1997) study also implied that the educational background is closely related to academic discourse practices and rhetoric. Leki's (2007) study is another exemplary research on language and literacy learning experiences of immigrant and international students throughout their entire undergraduate careers. In the multiple case studies, Leki (2007) argued that ESL composition courses may not be related to students' experiences of academic language and literacy in the U.S. academic setting and that L2 writing classes should provide international students with an opportunity to develop literacy skills and to learn academic strategies to overcome challenges of international students in academic adaptation. Cheng and Fox's (2008) study explored how international students were successfully engaged in the academic setting and developed more strategic learning and social skills as part of their adaptation process. The study examined factors of the participants' academic adaptation and a role of English for academic purposes (EAP) instruction as a mediator of academic adaptation processes. A grounded theory approach was employed in analyzing the responses elicited by semi-structured interviews with L2 students studying in three Canadian universities. The findings revealed that L2 students felt burdened in the new academic and cultural communities. A major issue was a mismatched agenda. Students' expectations and needs do not often meet the ones within their universities. For this reason, successful academic adaptation may not take place with language or disciplinary learning alone. Academic adaptation is such a complex process in international students' personal, social, intellectual, and cultural lives and cannot be a one-way communication from specialists in a target community to novice learners. As Cheng and Fox (2008) indicated, an adaptation process is so complicated and vibrant that second language researchers should investigate international students' academic adaptation processes with different perspectives.

2.2. Lexical Bundles as a Part of Academic Literacy Adaptation

Language is considered as formulaic in nature (Ellis, Simpson-Vlach, & Maynard, 2008; Sinclair, 1991). Formulaic language is significant in academic writing (Biber, Johansson, Leech, Conrad, & Finegan, 1999). Lexical bundles are the most frequent sequences of words in a language (Biber, et al., 1999), considered as a subcategory of formulaic language. Qin (2014) asserted that the appropriate usage of formulaic language leads second language learners to keep their identity in a disciplinary community. Many corpus researchers (e.g., Biber, et al., 1999; Cortes, 2004; Sinclair, 1991; Stubbs & Barth, 2003) have examined lexical chunks in texts and indicated that there are patterns of the lexical bundle use across different registers—academic prose, fiction, and conversation (Biber et al., 1999; Stubbs & Barth, 2003). Ellis, Simpson-Vlach, and Maynard (2008) also claimed that formulaic language provides meaningful implications: (1) a high utility of formulaic expressions, (2) the integration of formulaic language into the learning curriculum, (3) the determination of learnability and processing fluency, and (4) needs-based developmental instruction of

formulaic language. Second language researchers (e.g., Carroll, 2002; Harris, 1989; Hyland, 2009; Leki, 2007) maintained that adapting to the rhetorical styles and writing expectations of different disciplines is crucial in learning to gain membership in academia. Hyland (2008a) believes that second language learners become familiar with lexical bundles by participating regularly in the target community. They will be able to ultimately obtain a natural language use and reach a qualified language use.

Despite a useful indication of academic adaptation, lexical bundles have been disregarded due to the nature of incompleteness (Conrad & Biber, 2004). However, Hyland (2008b) maintained that lexical bundles are a key way of “helping to shape text meanings and contributing to our sense of distinctiveness in a register” (p. 5). Qin (2014) also affirmed that explicit instruction is necessary for the attainment of the lexical bundle use. Future research on lexical bundles is critical in diverse registers so that the research can be applied to second language writing pedagogy.

3. METHODS

3.1. Research Design

This study is based on corpus-based research. The research site was the English as a Second Language (ESL) Programs at a Mid-western university in the U.S. A textual analysis was employed for identifying the participants’ writing patterns in a learner corpus with regard to lexical bundles in corpus research.

3.2. Sample

This study used convenience and purposive sampling. With the approval of the ESL Program Office, two graduate composition classes were assigned and selected according to the researcher’s criteria (i.e., international graduate students) as purposive sampling. During the observation period for the research, three participants were selected for this study. Their participation was voluntary. The participants’ demographic information is provided in Table 1.

Table 1. Participants’ demographic information

Participant*	Gender	Nationality	Age Band	Pursuing Degree	Field of Study	Years in the U.S.
Hoon	Male	Korean	30-32	PhD	Architecture	10 months
Jisoo	Female	Korean	27-29	PhD	Nursing	10 months
Liwon	Female	Korean	33-35	MA	Education	10 months

* All the participants’ names are pseudonyms.

3.3. Instrumentation

The three participants’ final written products were collected and used for this study. The students’ final product was a critical review on a topic of their own choices from the

individual field of study. The length of the final product varied, but the students in the composition classes had to write at least 4,000 words with an appropriate format of critical literature reviews. The learner corpus data of the three participants included 12,941 words.

3.4. Data Analysis

Corpus researchers (e.g., Granger, Kraif, Ponton, Antoniadis, & Zampa, 2007; Nesselhauf, 2004) claimed that native corpora may not uncover learners' difficulty in second language writing. Learner corpora, however, can reveal specific challenges and difficulty in speaking or writing. Grander et al.'s (2007) study showed that learner corpora enable researchers to identify characteristics of a learner language by separating it from the target language. Hence, it is applicable to use a learner corpus for investigating international students' academic adaptation through second language writing. The data analysis began with clearing the corpus text without any non-text components (e.g., graphics, formulas, page numbers, references, tables, and figures) aligned with the requirement of *AntConc* software (Version 3.4.4) (Anthony, 2015). To analyze structural and functional characteristics of lexical bundles, the function of clusters/N-Grams was utilized in identifying four-word lexical bundles and clarifying whether they did not overlap in the *AntConc* software program.

Bal (2010) considers *AntConc* as a resourceful analysis tool for both quantitative and qualitative data in research. In the *AntConc* software, the N-Grams function enables the researcher to identify the count of “*n*” from the uploaded corpus. After a list of four-word bundles was extracted, I manually checked each lexical bundle whether it overlaps with other lexical bundles. Lastly, retrieved four-word lexical bundles were categorized into similar grammatical structures and functions based on their use and meanings in context by comparing the structural and functional taxonomies (Biber et al., 1999). Bal (2010) suggested that a second rater may assist the identification and classification of the lexical bundles for reliability of the data analysis.

Figure 1. Percentage distribution of nouns, prepositions, adjectives, and verbs between academic prose and students' writing samples.

4. FINDINGS

This section includes structural and functional characteristics of lexical bundles from the participants' corpus data.

4.1. Structural Characteristics of Lexical Bundles

To identify academic literacy adaptation from students' writing, structural features of lexical bundles were analyzed. The proportions of structural patterns in graduate international students' writing were compared to the ones in academic prose in Biber et al.'s (1999) lexical bundle project. Biber et al.'s (1999) project revealed that proportions of structural patterns in the academic prose include noun phrases (32%) and preposition with noun phrase fragments (33%). The present study uncovered a somewhat different trend from Biber et al.'s (1999) work. It showed 67 percent of noun phrases, taking up two-thirds of the entire bundles; 17 percent of preposition with noun phrase fragments. Another major structural pattern involved content-focused compound noun phrases, containing two or more words to make a single noun (23%) in international students' writing. Furthermore, specific disciplines of study, such as nursing and architecture, use technical terms (e.g., *the cell cycle regulation*) very frequently, with frequency counts of 15. Other structural patterns, such as anticipatory it + VP/-adjective phrase (+ complement clause) and passive verb + prepositional phrase fragment, have a similar trend to Biber et al.'s (1999) patterns. The rest of the three structural patterns, such as pronoun/NP (+ auxiliary) + copular be (+), (verb +) that-clause fragment, and (verb/adjective+) to-clause fragment, are not found in this study. This limited information would be because critical reviews were the only input of the written register, and the sample size is very small—three critical review papers with 12,941 word tokens.

4.2. Functional Characteristics of Lexical Bundles

This study yielded 39.82 percent of the functional use in the students' written register as the preliminary findings. Biber et al. (1999) highlighted three primary functions of lexical bundles in the registers: 1) stance bundles, 2) discourse organizers, and 3) referential bundles. Stance bundles refer to attitudes or assessments of certainty representing other propositions (e.g., *I do not know, I do not think*). Discourse organizers are relationships between preceding and forthcoming discourse (e.g., *what do you think, you know I mean*). Referential bundles indicate direct references to the textual context to identify a particular attribute of the entity (e.g., *one of the things, in terms of the*).

Two types of functions (i.e., stance and referential bundles) are found in the study. The proportion of attitude/modality stance, specifically with an obligatory function, comprises 6.48 percent with seven frequency counts (e.g., *it is necessary to*). The proportion of referential bundles with the function of place takes up 12.04 percent with 13 frequency counts (e.g., *in the cell cycle*). The proportion of referential bundles with tangible framing attributes takes up 21.30 percent with 23 frequency counts (e.g., *the impact of urban form, the development of PTSD, phenomenon of post ICU-PTSD*). 60.18 percent of the rest of lexical

bundles are all content-oriented combinations. For example, the most frequent bundle is 'the cell cycle regulation' with 15 frequency counts (13.89%).

4.3. Academic Literacy Adaptation through the Participants' Use of Lexical Bundles

Academic literacy adaptation was examined with structural and functional characteristics of lexical bundles in the participant's academic writing. First, the analysis of structural features showed that nouns are the most frequently used part of speech patterns, reflecting that the written registers pursue the primary informative purpose of writing; that is, critical reviews. Compared to the academic prose in Biber et al. (1999), nouns are much more common than other parts of speech (i.e., adjectives and verbs) in the students' writing samples.

For the functional characteristics, the analysis revealed that international graduate students tend to use a lot of technical terms from the previous literature focusing on unique disciplines when they write critical reviews. Nine out of 14 types of lexical bundles were topic-specific bundles. For example, *cell cycle regulation* and *in the cell cycle* are technical terms in the discipline of nursing, regardless of any lexical functions.

Table 2. The summary table of lexical bundles in the corpus of the final critical review papers

Lexical bundles	Structure	Function	Frequency	%
the cell cycle regulation	NP	Topic-specific	15	13.88
in the cell cycle	PP	Referential-place	13	12.04
impact(s) on travel behavior	NP	Topic-specific	11	10.18
impact of urban form	NP	Referential-framing attributes	9	8.33
the development of PTSD	NP	Referential-framing attributes	8	7.41
form on travel behavior	NP	Topic-specific	7	6.48
it is necessary to	VP	Stance- obligation	7	6.48
involved in the cell	VP	Topic-specific	6	5.56
of the cell cycle	PP	Topic-specific	6	5.56
phenomenon of post ICU-PTSD	NP	Referential-framing attributes	6	5.56
RB/E2F pathway and dream complex	NP	Topic-specific	5	4.63
of the development of	PP	Topic-specific	5	4.63
solve the problem of	VP	Topic-specific	5	4.63
three argumentative organizational plans	NP	Topic-specific	5	4.63
Total	14		108	100
Total word tokens: 12,941				

5. DISCUSSION

5.1. Lexical Bundles as an Indicator of Academic Literacy Adaptation

Lexical bundles were investigated through corpus research to find out whether lexical bundles indicate academic literacy adaptation. In other words, the use of lexical bundles may be a potential indicator of international students' academic literacy adaptation. Lexical bundles include two characteristics: structural and functional (Biber et al., 1999). In terms of structural features, the participants' lexical bundles were found to follow the trend of the most frequent used noun phrase fragments from Biber et al.'s (1999) work. In particular, topic-specific compound noun phrases were most frequently used due to a certain written register; that is, critical reviews. Thus, the writing samples tend to exhibit the information about the specific expertise from previous literature.

As for the functional use of lexical bundles, two types of functions (i.e., stance and referential bundles) were found with 43 frequency counts (40%) among the 108 lexical bundles. Discourse organizing bundles were not found, but this may be attributed to the small sample size. In Biber's (2006) study, the proportion of discourse organizing bundles in the registers of textbooks and academic prose is far less than conversation and classroom teaching. Hence, it may be natural that no discourse organizing bundles existed in such a small corpus with 12,941 word tokens. The functional use of lexical bundles was not represented as meaningful in the findings due to the small sample size. However, it may be true that the students may not express their own voices in critical reviews due to no use of discourse organizing bundles. Rather, they are likely to write carefully to involve the original articles with sincere understandings. This also shows their academic adaptation regarding the rhetoric: international students' tendency to veil their stance or arguments in critical reviews. To make this study meaningful, it is needed to accumulate more writing samples to represent international students' academic literacy adaptation.

6. LIMITATION

Several limitations need to be addressed for enhancing future research. First, this study examined academic literacy adaptation with the small size of the learner corpus. Since the sample size is relatively small, the results cannot be generalizable. With the small sample size, the corpus data were also too small to be analyzed or interpreted for the legitimate proposition. Second, the duration of the research was short in collecting the students' written product and observing their writing patterns. If the corpus data were accumulated in a longer period of time, it would be possible to retrieve more representative findings. Finally, pre- and post-observations of lexical bundles could have revealed a more logical connection between academic literacy adaptation and the use of lexical bundles. For example, it would have been optimal to compare their initial writing products at the beginning to the final writing products at the end of the research.

CONCLUSION

The significance of the research is to understand the international graduate students' academic literacy adaptation through corpus research. This study provides potentials for researchers to implement corpus research to explore academic literacy adaptation by examining lexical bundles, a linguistic component in a language. Despite the small sample size, the study yielded structural (67% of noun phrases) and functional (39.82% of stance and referential) features, and this uncovered some trend of international graduate students' academic literacy adaptation.

Future research needs more improvement. First, more samples are necessary in developing valid and reliable corpus research so that the results can be representative and generalizable. Second language writing samples should be accumulated for significant contributions to the corpus research. Furthermore, examining different genres of writing and registers (i.e., spoken and written) would provide a lot clearer essence of lexical bundles in second language writing. The future research should also connect the information and knowledge of lexical bundles to second language learning instruction and pedagogy. Qualitative research may help uncover in-depth understandings of international students' academic adaptation with qualitative-oriented research techniques, such as observations, field notes, interviews, and verbal protocols, which should be practically employed for yielding valuable research findings.

**MULTISEMIOTIC ANALYSIS OF ORTHODOX
PATRIARCHS' PHOTOGRAPHS:
CROSS-CULTURAL (INDIAN AND RUSSIAN)
DIFFERENCES IN INTERPRETATION OF
INTERACTIVE MEANINGS**

ABSTRACT

The paper investigates the role of the implementation of the multisemiotic theory through the analysis of the Orthodox Patriarchs' photographs. The research is based on the multisemiotic theory by Kress and van Leeuwen and supports the view that semiotic codes are used in specific historical, cultural and institutional contexts. It is customary for people to communicate the meaning referring to various codes, depending on the contexts, as codes are not only planned, taught, justified, but also criticized. The authors of this paper make an attempt to prove the hypothesis that Russian and Indian respondents code similar photos differently due to their cultural/ideological backgrounds. According to Kress and van Leeuwen, pictures are images that convey an interactive meaning. Thus, the main focus of the research is on the image viewer interaction. The present study examines the data obtained from 526 official photographs of the Patriarchs and consists of several stages. At the first stage two groups of coders (Indian and Russian) were created. The selected groups were provided to code the collected corpus of photos (in total 526 photographs) autonomously. In case of discrepancies between the

* Corresponding Author Email: spgbu@list.ru.

coding images, the agreement was terminated by two national coders collaboratively. At the second stage, the semi-structural interviews with the coders were conducted. The interviews allowed to identify and reveal similarities and differences in photo perception. The results of the study show, that the multisemiotic theory can be entirely employed and serve as an effective tool in image analysis within different cultures through identifying the interpersonal (interactive) metafunction. As the research demonstrates limitations like small amount of studied samples and a low number of Indian participants' opinion provided in the Russian Federation, further research in India is recommended.

Keywords: multisemiotic theory, interpersonal (interactive) metafunction, cross-cultural differences, Orthodox Patriarchs' photographs

1. INTRODUCTION

The current paper explores the characteristic features of the interactive meanings of the Orthodox Patriarchs' photographs. In this respect Kress and van Leeuwen state that "The interactive meanings are visually encoded in the ways that rest on competencies shared by producers and viewers" (Kress & van Leeuwen, 2006: 115). The photographs' interactive meanings may partially change not only the viewers opinion in image perception, but also, to some extent, social representation of the church ideology. In order to apprehend why some photographs are more amiable than the others, producers and viewers' intentions and interpretations have to be identified and considered compulsively.

Although the interactive meaning is a common concept of interaction with many social science, for example, sociology or systemic functional linguistics (SFL), it has often been distinguished as being related to the interpersonal metafunction (see Halliday & Matthiessen, 2014: 30). The SFL approach shares the overriding assumption that "We use language to make sense of our experience, and to carry out our interactions with other people. This means that grammar has to interface with what goes on outside language: with the happenings and conditions of the world, and with the social processes we engage in. But at the same time it has to organize the construal of experience, and the enactment of social processes, so that they can be transformed into wording" (Halliday & Matthiessen, 2014: 25).

It is claimed that modern pragmatics is not limited by reflecting society and language in contrast with events and social processes. However, the new perspective called "embodiment" and the role of the human body are being disadvantaged (see Lakoff & Johnson, 1980). The embodiment approach confirms that a human body is mostly accepted identically throughout the world. This fact predetermines a lot of questions and creates a new scope for the cross-cultural research. Recent developments have shown an increased interest in the embodiment of photographs and have highlighted it as one of the primary objectives for further investigation. So, the current study shares the view that the cross-cultural differences in identifying the interactive meanings can be fully explained in terms of the SFL-based multisemiotic theory, similar to Kress and van Leeuwen theory. The controversy about embodiment is connected with the process of distinguishing a human body as cultural and social product, because society and social institutes dictate the patterns of behaviour and draw boundaries for body perceptions.

Thus, this paper claims to apply and illustrate Kress and van Leeuwen multisemiotic theory's analysis of the Orthodox Patriarchs' photographs within the context of Indian and Russian cross-cultural study. The topicality of the research concerns the theoretical application and the data set. Theoretical significance is revealed in the attempts to apply western - origin multisemiotic theory to two selected types of non-western perceptions of the Orthodox Patriarchs' photographs, using a model for the analysis of interpersonal metafunction of images. The concern expressed by Kress and van Leeuwen is related to the relevance of application of the multisemiotic theory in non-western environment (Kress & van Leeuwen, 2006:3). It can be argued that a similar approach to sociological content analysis assumes that standardization of procedures and control of inter - rater reliability can give information about differences and similarities in cross-cultural perception (see e.g., Yadov, 2007). The corpus data of this paper comprises 526 photographs dealing with the specialized topic called Orthodox Church Patriarchs' activity. The significance of statistical information is proved by the expanded corpus sample.

The selection of Patriarchs' photos as a material for the research can be explained by the similarity in the tendencies to expand both on the part of Christian and Orthodox Churches (see e.g., Foundations of Social Concept of the Russian Orthodox Church, 2000). However, the mission policies of the Constantinople and the Moscow Orthodox Church Patriarchate are distinct (see e.g., The Nature and Mission of the Church, 2011). For example, The Moscow Patriarchate is sensitive towards its territorial issues, while the Constantinople Patriarchate supports the external mission. As the result, Australian Orthodox Church (ROCOR, 2016) has recently opened several Orthodox Church Associations in India (see Pavlenkov, 2015). Therefore, it comes out of question that Indians might have different perception of the Orthodox concepts and specific attributes, including icons, images and photographs. Aimed at establishing new contacts between India and Russia, the Indian Orthodox community in Bangalore addresses the authors of the article to conduct a preliminary study devoted to the comparison of Indian and Russian perceptions of the Orthodox Patriarchs' photographs.

This study is not aimed at and does not put much emphasis on the Orthodox icons identification, since the icons are recognized entirely as church possessions and attributes. The newly involved church members always have an opportunity to be familiarized with the icons as soon as the interest to Orthodox Church arises. The study is limited by the selection of photographs available in the media sources. They are usually photos of the Patriarchs as the main church officials.

As the main focus of the present paper is on Russia but not India, this explains the importance to examine the differences in the photos' interactive meaning perception placed in Russian environment. Moreover, Indians in Russia are familiar with Russian culture and do not need to gain extra knowledge or undergo educational or explanatory procedures on what the Orthodox Church is. In addition, Indians are considered as leaders, that have already adjusted to Russian environment, and in this relation can be viewed as an advanced group. The mentioned factors stress the importance of the current paper research.

Thus, the primary aim of the study is related to the multisemiotic analysis of the Orthodox Patriarchs' photographs with regard to the cross-cultural (Indian and Russian) differences in identifying the interactive meanings. Two main objectives have been determined.

Objective 1 focuses on the detection of the evident similarities and differences in the Indian and Russian perceptions of the interactive meanings of the Orthodox Patriarchs' photographs;

Objective 2 focuses on the analysis, to what extent the differences in the Indian and Russian perception of the interactive meaning can influence the description of church ideology represented in the Orthodox Patriarchs' photographs.

The *hypothesis* of the study is that Russian and Indian coders can code/decode photos distinctly because of the peculiarities of cultural/ ideological backgrounds. In terms of statistics, it means that the level of agreement in the homogeneous Russian or Indian group of coders is higher than in the mixed Russian and Indian group of coders.

2. THEORETICAL BACKGROUND

The photo analysis is considered to be a quite complex process despite the assumed simplicity in processing and interpreting photos. "Photographs are often used to bring a sense of immediacy and reality to the text in a way that promotes interaction with the reader" (Martínez Lirola, 2006: 253). Moreover, it is difficult to describe the meaning of the photos applying analytical and research tools. This is explained by the lack of discussions conducted around the social and linguistic meaning of the photos, and little attention is drawn on the part of the social researchers. Roland Barthes supports the concern and lists some reasons for the analysis of "the air of a face": "The air of a face is unanalyzable (once I can decompose, I prove or I reject, in short I doubt, I deviate from the photograph, which is by nature totally evidence: evidence is what does not want to be decomposed)" (Barthes, 1981: 107-109).

Roland Barthes's contribution has been taken as a basis for the further investigation of the photographs as multimodal social phenomenon. Speaking about "the ways in which the meanings of photographs have been framed and adjudicated", John Tagg notes that these ways are tightly connected with "the institutionalized function of the photograph as a privileged form of evidence which has been so important to certain processes of power" (Tagg, 2009: XV-XVI). From this point of view, the social aspects of the photographs cannot be examined in isolation from their ideological function. To some extent, it is a focus on ideology that recognizes the power hidden in the photos (Breckner, 2008; Schill, 2012).

In Russia there are few studies that take the similar stance. The first reason is that through the decades Russian scientists have been researching the photos of Soviet leaders with the evident reflection of the Soviet ideology (see e.g., Ventsel, 2010; Oreh, 2012). Moreover, it is generally thought that Soviet and Russian photos have been considered as the main source of power and social phenomenon. The vast majority of the research papers confirm (Pavenkov et al., 2014), that ideology is an important factor of human perception. However, there is a drawback of the researches of that kind, which is hidden in the subjectivity of interpretation. Finally, until the end of the 1990s, the majority of social researchers considered photos as material with potential gaps and weaknesses for the scientific analysis, material that lacks academic integrity, science capability and information.

In contradiction with the mentioned works that identify the ideology of the photos directly and literally, social semiotics focuses on the description of "semiotic resources" (Jewitt & Oyama, 2001: 134). Social semiotics argues that the key value of the visual

resources is an ability to reproduce the potential meanings. Accordingly, resource description is not a description of the single meaning; it is a description of the limited set of possible meanings that are created by the authors and the viewers during their participation in the process of image interpretation (Jewitt & Oyama, 2001: 135).

Kress and van Leeuwen achievements in photo analysis make the scientific breakthrough in the image processing (see e.g., Kress & van Leeuwen, 2006). The scientists have developed and offered methodological tools which investigators can apply to define, extract and explain the photo meanings. While expanding the research conducted by the linguist Michael Halliday, Kress and van Leeuwen argue that the visual mode must perform certain visual and communicative metafunctions: ideational, interpersonal and textual (Kress & van Leeuwen, 2006: 42-43). Employing various visual elements, an image-producer influences the way a viewer has to eye a photograph or a picture. Ideational and interpersonal metafunctions highlight characteristics of the composition while the textual metafunction gives the possibility to explore the overall composition of the image (Kress & van Leeuwen, 2006: 40-42).

Kress and van Leeuwen have noted (2006: 14) that they seek the regularity in the usage of the different visual elements in visual communication systems. Thus, the primary goals of their investigation are not simply aimed at revealing the reasons of the usage. Respectively, Kress and van Leeuwen believe that each image contains the expression of ideological positions, and cannot be considered as an objective image of reality (2006: 14). It means that serious cross-cultural differences in interpretation are possible. In their reports, Kress and van Leeuwen point out: "Meanings belong to culture, rather than to specific semiotic modes" (Kress & van Leeuwen, 2006:2). They either write the following: "In the book we have, by and large, confined our examples to visual text-objects from 'Western' cultures" (Kress & van Leeuwen, 2006:3).

Taken above said into consideration the following question arises, whether it is possible to apply the multisemiotic theory to the analysis of the Orthodox Patriarchs photos, which are the product of Russian culture and Russian perception. More than that, the Indians involved in the study are also considered as representatives of non-Western cultures. However, soon after establishing the west-oriented direction and the nonuniversality of their visual grammar, Kress and van Leeuwen suggest that in spite of the specific cultural setting it can bring some benefit to non-Western cultures (Kress & van Leeuwen, 2006:3).

In respect of ideology, it can be said that, due to the perception varieties, photos in distinct cultures may establish different ideology. If the Russian photographer supposes to convey a certain meaning, the result may be completely different in another culture and the photo might create an unexpected ideology. Therefore, photos' ideology is not a constant but provides the meaning potential where "the meaning potential is the range of significant variation that is at the disposal of the speaker" (Halliday, 1971: 171).

Since the present paper hypothesis assumes that the Russians and the Indians perceive photos differently, the current study is focused mainly on the interaction between a viewer, a producer and photos' represented participants that focus on the interpersonal metafunction. M.A.K. Halliday was the first linguist who described the interpersonal metafunction (see Halliday and Hasan, 1985, Halliday 1978, 1985, 2003, 2014). He proposes that "Language is always also enacting: enacting our personal and social relationships with the other people around us" (Halliday & Matthiessen, 2014: 30). According to Halliday, "We inform or question, give an order or make an offer, and express our appraisal of or attitude towards

whoever we are addressing and what we are talking about. This kind of meaning is more active, this is language as action. We call it the interpersonal metafunction, to suggest that it is both interactive and personal” (Halliday & Matthiessen, 2014: 30).

Relating to the image, the interpersonal metafunction is shown through the relationship between the represented participant(s) and the viewer/reader. Furthermore, the relationship is established between the image producer and the viewer. In other words, a creator (an author) of an image may code how the viewer has to watch this image and its represented participant(s). Kress and van Leeuwen call the creator and the viewer as “interactive participants”. Interactive participants are “real people who produce and make sense of images in the context of social institutions which, to different degrees and in different ways, regulate what may be 'said' with images, and how it should be said, and how it should be interpreted” (Kress & van Leeuwen, 2006: 114). At the same time, “Producer and viewer know each other and are involved in face-to-face interaction, as when we take photographs of each other to keep in wallets or pin on pinboards. But in many cases there is no immediate and direct involvement. The producer is absent for the viewer, and the viewer is absent for the producer” (Kress & van Leeuwen, 2006: 114).

As the result three types of relations between the participants are established: “(1) relations between represented participants; (2) relations between interactive and represented participants (the interactive participants’ attitudes towards the represented participants); and (3) relations between interactive participants (the things interactive participants do to or for each other through images)” (Kress & van Leeuwen, 2006: 114). The identified relationships can be studied with the help of the relatively simple indicators, that are reflected in the photos and create the interactive meanings. They are *contact*, *social distance* and *attitude* (see Figure 1).

Figure 1. The interactive meanings in images (Kress & van Leeuwen, 2006:149).

1. *Contact*. Usage of the “view” (gaze) assists in establishing relationships between the viewer and a certain person in the image. The concept of the contact is particularly

important for the research because the prevailing majority of photographs or picture books may contain the image of a person. In this context, the view is understood as a situation where the portrayed person looks directly at the viewer. Kress and van Leeuwen (2006: 122) assert that the depicted person addresses the viewer directly and requires something from him/her. The specific nature of the established relationship between the depicted person and the viewers depends on additional information obtained by the other methods (e.g., facial expression or gestures). What is more, the gaze which is directed at something else in the image but not at the viewer is also significant. In this case, the viewer can observe the person indifferently without personal involvement excluding relationship or interaction. Thus, the "contact" can be encoded as "demand" or "offer". For the coders "demand" can be indicated as "gaze at the viewer"; "offer" as "absence of gaze at the viewer" (see Kress & van Leeuwen, 2006: 148).

2. *Social Distance*. Social distance is described as a physical distance between the depicted people and the audience. It means that physical distance is the size of the object in the image that creates visual impression of the distance spread from the viewer to the object. Physical intimacy is established with the audience, similar to people in real life. Physical intimacy represents social proximity, close relationship between the viewer and the object.

People in the photos are often put into and associated with particular locations (e.g., the Patriarch in the Church, meeting of the Patriarch and the Pope at the airport), consequently the photographs are likely to indicate the location. The visual representation of the location distinguishes between the foreground, that means being more prominent or more salient, and the background, that means being less prominent. To illustrate this, the objects in the locations can be of different shapes and sizes. Photographs usually demonstrate not only singularity or plurality of the objects but their interaction. Eventually, three locations or three distances are known as:

1. The close distance shows the situation and the objects with the viewer involved into.
2. The middle distance supposes that the situation and objects are shown in overall dimension without much space around them.
3. The long distance where the situation and objects are shown for contemplation only.

Kress and van Leeuwen offered the following respective types of "distance": intimate/personal, social or impersonal. Intimate/personal distance or close personal distance is the distance at which "one can hold or grasp the other person and therefore also the distance between people who have an intimate relation with each other" (Kress & van Leeuwen, 2006: 124). Social distance or far personal distance is the distance at which subjects of personal interests and involvements are discussed (Kress & van Leeuwen, 2006: 124). Impersonal distance is "public distance" (Kress & van Leeuwen, 2006: 125). In the process of coding the photos "distance" can be encoded as intimate/personal, social or impersonal. For the coders intimate/personal distance can be indicated as "close shot", social distance as "medium shot", impersonal as "long shot" (see Kress & van Leeuwen, 2006: 148).

3. *Attitude*. An attitude represents the structure that is complex and includes subjective and objective setting (see Figure 1). Subjectivity attitude includes two groups of indicators:
 - Involvement and Detachment;
 - Viewer power, Equality and Represented participant

An objectivity attitude refers to “scientific and technical pictures, such as diagrams, maps and charts” (Kress & van Leeuwen, 2006: 143) and is not considered in the current research.

Involvement and Detachment

Kress and van Leeuwen contend, that the horizontal point of view determine the level of involvement and detachment in the created image both on the part of the producer and the viewer. The level of involvement is established with the help of the angles that fall into different groups. Consequently two basic types of angles are identified:

- a) Horizontal angle is “the function of the relation between the frontal plane of the image-producer and the frontal plane of the represented participants” (Kress & van Leeuwen, 2006:141). These relations can be parallel or form an angle. Kress and van Leeuwen suppose that the frontal angle acts similar to “what you see here is part of our world, something we are involved with” (2006: 143). The frontal angle is an angle of maximum involvement. It is oriented towards the action (Kress & van Leeuwen, 2006: 145).
- b) The concept of “oblique points” from Kress and van Leeuwen’s point of view can be stated like “What you see here is not part of our world, it is their world, something we are not involved with” (2006: 143). In the process of coding photos in this paper, “*involvement*” can be indicated as “*frontal angle*” and “*detachment*” can be indicated as “*oblique angle*” (see Kress & van Leeuwen, 2006: 148).

Viewer Power, Equality and Represented Participant Power

One of the aspects of the photo analysis is the connection between the represented participants, here the Patriarchs, and the observer, called perspective. The use of the perspective includes two practical tasks:

1. Selecting a certain frame size which in practice involves selection of an angle, called the point of view.
2. Welcoming the possibility of expressing the subjective attitudes which presupposes the personal evaluation of the viewers toward the action of the represented participants (Kress & van Leeuwen, 2006:135).

The angle in the current paper deals with the notion of power, ignoring the notion of involvement. This angle is known as vertical angle and within it we have to look at the low angle, the high angle, and the eye level. The high angle makes the observed subject small and

insignificant. High angles tend to diminish the individuals and humiliate them morally by reducing them to the ground level in an insurmountable determinism (Martin, 1968: 37-8). If the represented participant is viewed from a high angle or from up to down, it means that the viewer has power over the represented participant. In addition, if the photograph is placed at eye level, then the point of view is one of the equality and there is a power difference involved (Kress and van Leeuwen, 2006:146). In the process of coding of the considered photos, “viewer power” can be indicated as high angle, “equality” can be indicated as eye-level angle and “represented participant power” can be indicated as low angle (see Kress & van Leeuwen, 2006: 148).

Kress & van Leeuwen (2006: 127,139) explore the term “system” for denomination “contact”, “social distance” etc. They write: “Unlike the system of “offer” and “demand”, the system of social distance can apply also to the representation of objects and of the environment”, “And, while in language one cannot easily have degrees of “ourness” and “theirness”, in images such gradation is an intrinsic part of the system of involvement. Finally, there is no “yours” in the system of horizontal angle” (see Kress & van Leeuwen, 2006: 127,139).

Thus, based on Kress & van Leeuwen (2006: 148), this research borrows the mentioned codes for the coders, who have to refer to the table descriptors during an encoding process (see Table 1).

Table 1. Interpersonal metafunction's codes for photos

System	Code	Description
Contact	Demand	gaze at the viewer
	Offer	absence of gaze at the viewer
Social Distance	Intimate/personal	close shot
	Social	medium shot
	Impersonal	long shot
Subjectivity Attitude	Involvement	frontal angle
	Detachment	oblique angle
	Viewer power	high angle
	Equality	eye-level angle
	Represented participant power	low angle

3. DATA AND METHODOLOGY

In order to check the hypothesis, two-stage research has been conducted with the focus on the identification of the main differences between the Indian and the Russian perception of the ideology of the Russian Orthodox Church in the Patriarch's photos. The selected photographs of Patriarchs Alexey II, Kirill and Bartholomew have constructed the corpus. The whole photos' corpus includes 526 photos taken from the official Orthodox Church website. The major part of the photos presents the activity of Patriarchs Alexey II, Bartholomew and Kirill (Gundjaev), who is well known as an active Church writer (see Gundjaev, 2009).

The research procedure of the present study goes through the following stages:

Stage I. Coding the whole photos' corpus by four coders. Two Russian and two Indian students, called coders, made a special group trained on the SPSS program. Coders were instructed purposefully how to use SPSS's program (SPSS v.17) for coding. They were provided with coding descriptors composed in accordance with Kress and van Leeuwen' theory (see Table 1). Firstly, coders read through the codes descriptors, discussed criterions, after that two Russian and two Indian students coded 526 photographs separately. The importance of the result analysis at this stage was determined by the coding procedure.

The first stage addressed the research question whether there is a statistically significant difference in the Indian and Russian coding of the whole photos' corpus. In order to answer this question, four coders handed coding results to the instructor in the form of sav. files (SPSS). The instructor measured the level of agreement (inter-rater reliability) between two Indians and two Russians, using the Cohen's Kappa κ coefficient (Cohen, 1960, 1968; Fleiss et al., 1980; Fleiss et al., 2003). This coefficient is applicable but restricted to pair work because of its ability to measure the level of agreement between two experts. After that the level of agreement between four pairs of Russians and Indians was calculated. Finally, the excel tables were filled in and schemes organized for the results presentation.

Website Dfreelon.org was used to calculate Krippendorff's alpha in order to check the statistically significant difference between four coders. According to the description of Krippendorff's alpha coefficient, sufficiently high degree begins from 800. Scientists generally rely on data reliability $\alpha \geq 0.800$. If the data lies between $0.800 > \alpha \geq 0.667$ the findings are considered as preliminary. If data reliability is low ($\alpha < 0.667$) the findings cannot be found.

Stage II. Semi-structured interview with coders. The second stage of the research process involved "face to face" semi-structured interviews, which were carried out in July 2016 in St. Petersburg. Semi-structured interviews with the Indian coders were conducted in English, with the Russian coders in Russian language, respectively. The data gained from the semi-structured interviews with two Russian and two Indian coders made ($N_c = 4$) after their coding of the whole photos' corpus. The second stage of the research addressed the following research question: how did two Indian coders and two Russian coders overcome problems they encountered during coding the whole photos' corpus?

4. RESULTS

4.1. Stage I. Results of Coding the Whole Photos' Corpus ($N_c = 4$, $N_{ph} = 526$)

In line with the research question this section presents the results of the analysis of coding the whole photos' corpus ($N_c = 4$, $N_{ph} = 526$) using data collected in the small-scale research.

4.1.1. Contact

The review of Kress and van Leeuwen theory reminds that the researchers distinguish between the pictures, where represented participants look directly at the viewers, and the pictures with the absence of gaze at the viewer. The first are named “demand” and second are named “offer” systems (see Kress & van Leeuwen, 2006: 122,148). It is important for the objectives of the present study to measure the *inter- rate reliability* between coders. So, the authors of this paper started with an overview of *inter - rate reliability* (Cohen’s Kappa κ ; Krippendorff’s alpha α) for the system of *contact* (see 4.1.1.1), then the results of *contact* coding were given (see 4.1.1.2.).

4.1.1.1. Overview of Inter-Rater Reliability (Cohen’s Kappa κ ; Krippendorff’s Alpha α)

In order to test the hypothesis it is important to use Cohen’s Kappa (Cohen’s Kappa κ) coefficient, which is a statistic which measures inter-rater agreement for qualitative (categorical) items. The measure of agreement Kappa is taken because it can be used for the analysis of more subjective evaluations (see: Oleinik, Popova, Kirdina & Shatalova, 2013). Unlike Krippendorff’s alpha, the calculation of Cohen’s Kappa shows the degree of random agreement that is interpreted in terms of the constancy with which a coder conducts categorization of units of analysis (Artstein & Poesio, 2008: 561, 570). From this point of view, the final row and column of contingency table indicate the preferences and prejudices of the coders (Perreault & Leigh, 1989: 139), although do not indicate the actual distribution of units as it happens in the case of Krippendorff’s alpha. Originally Kappa is calculated for the case with two coders. The value of Cohen’s Kappa is defined as:

$$\kappa = \frac{P_o - P_e}{1 - P_e}$$

where p_o is the relative observed agreement among raters, and p_e is the hypothetical probability of a chance agreement, using the observed data to calculate the probabilities of each observer (Seale, 2011: 462). This formula is later generalized to the case of the plurality of coders (Siegel & Castellan, 1988: 285).

The most important assumption is that “probability that an object is assigned to a particular category does not vary across raters” (Siegel & Castellan, 1988: 291). Coders agree because they share similar opinions or similar values. Despite the subjectivity of their decisions they manage to come to an agreement.

The focus change from the natural distribution of categories (in the case of *Krippendorff’s alpha*) to subjective judgments of the coders (in the case of *Cohen’s Kappa*) leads to the resistance from apologists of Krippendorff’s alpha. It is believed that Kappa “concerned with the two individual observers, not with the population of data they are observing, which ultimately is the focus of reliability concerns” (Krippendorff, 2004: 248; see also Hayes & Krippendorff, 2007: 81). Nevertheless, Kappa and Krippendorff’s alpha can refer to different dimensions of reliability: if the first characterises the reliability of judgments, Krippendorff’s alpha mainly characterizes the reliability of data.

In order to combine two strategies in the present research, both coefficients are considered. In the case of identification of similarity/ differences between two Russian and two Indian coders, *Cohen's Kappa* is measured. However, there is a need to use *Krippendorff's alpha* in order to show similarity/distinction between all four coders and check *Cohen's Kappa's* results. A list of *Cohen's Kappa* interpretation (Landis & Koch, 1977) is given in Table 2, a list of *Krippendorff's alpha* interpretation (Krippendorff, 2004) is given in Table 3.

Table 2. Interpretation of the *Cohen's Kappa* agreement

Cohen's Kappa	Interpretation
< 0	Poor agreement
0.0 – 0.20	Slight agreement
0.21 – 0.40	Fair agreement
0.41 – 0.60	Moderate agreement
0.61 – 0.80	Substantial agreement
0.81 – 1.00	Almost perfect agreement

Table 3. Interpretation of the *Krippendorff's alpha* reliability

Krippendorff's alpha	Interpretation
$\alpha < 0.667$	data reliability is low; we cannot make any conclusions
$0.800 > \alpha \geq 0.667$	preliminary conclusions
$\alpha \geq .800$	data reliability is high

The coders in the research were named like Indian 1, Indian 2 and Russian 1, Russian 2. Based on the description of statistical coefficients, the coefficients were calculated with the help of SPSS program and website (dfreelon.org). *Cohen's Kappa* was calculated for “*contact*” for each pair of coders. These data are presented in Table 4.

Table 4 shows that *Cohen's Kappa* between two Indians is 0,762. Value 0,762 means substantial agreement. Further, still the calculation shows $p = 0,000$. It is needed to note that the level of agreement between Russians coders is high ($\kappa = 0,862$). It means almost perfect agreement. The relationship is statistically significant ($p = 0,000$).

Table 4. Result of Inter-rater reliability (*Cohen's Kappa* κ) for *Contact*

	Indian1	Indian2	Russian1	Russian2
Indian1	X	0,762	0,582	0,538
Indian2	0,762	X	0,487	0,487
Russian1	0,582	0,487	X	0,862
Russian2	0,538	0,487	0,862	X

Note: Green colour shows Substantial and Almost perfect agreement and red colour shows Moderate and Fair agreement.

Table 5. Value of Krippendorff's alpha for system of contact

Krippendorff's alpha (ordinal)	0.606	N coders:	4
Krippendorff's alpha (interval)	0.606	N cases:	526
Krippendorff's alpha (ratio)	0.606	N decisions:	2104

In contrast, the value of agreement's coefficient between coders from different countries is lower, and, referring to interpretation of Cohen's Kappa, it means moderate agreement. Between Russian 1 and Indian 1 the value of measure of Cohen's Kappa is 0,582, between Russian 1 and Indian 2 the value of measure of Cohen's Kappa is 0,487, between Russian 2 and Indian 1 the value of measure of Cohen's Kappa is 0,538 and between Russian 2 and Indian 2 the value of measure of Cohen's Kappa is 0,487. Complementary calculation of Krippendorff's alpha assures that the degree of agreement in the encoding of "*contact*" between coders of international team is low (see Table 5).

Krippendorff's alpha proves that measure of agreement ($\alpha < 0.667$) is low and difference between the Russians and the Indians are statistically significant. Thus, referring to the system of *contact* it means disagreement between Russian and Indian coders. At the same time, Kappa confirms the high degree of agreement between the Indians ($\kappa = 0,762$) and the Russians ($\kappa = 0,862$).

4.1.1.2. Results of Contact Coding ($N_c = 4$; $N_{ph} = 526$)

The results of contact coding are presented in Table 6. It is clearly stated that among Indian and Russian coders "*demand*" exceeds "*offer*" in the whole photos' corpus. Nevertheless, the difference between the Russians and the Indians is evident (see Table 6).

Table 6 presents the number of photographs encoded by the Indians as "*demand*". It is ranged from 81.2% to 81.6%. In comparison, the coding of "*demand*" by the Russians fits the diapason from 64,1% to 66,5%. The analysis of the differences reveals the examples of the full consent and the full absence of agreement in encoding. Thus, Figure 3 "The meeting of the Patriarch with Naryshkin in Patriarch's residence" and Figure 4 "The meeting of the Patriarch with a foreign delegation" are examples of full agreement in the coding of "*contact*" between Russian and Indian coders. Presumably, it is caused by the fact that Patriarch and his guests look directly at the viewer, and there is no doubt that it is a "*gaze at the viewer*" (see Figures 3, 4).

Table 6. Results of coding of *Contact*

	Indian 1	Indian 2	Russian 1	Russian 2
Demand	81,6	81,2	66,5	64,1
Offer	18,4	18,8	33,5	35,9
Total	100	100	100	100

The presented below pictures cause particular difficulties in identification. An ambiguity in the pictures is recognized as it is not easy to identify whether the Patriarch looks straight at the viewer or not. It has to be noted that in both figures (see Figures 5, 6) the Indian coders' preferences lie with "*demand*", while the Russians mention "*offer*". Presumably, the Indians evaluate miniature eye movements as inconsiderable. On the other hand, from certain angles

it seems that the Patriarch looks at the viewer. As for (see Section 5) the Russian coders, they demonstrate the tendency to encode “*contact*” as “*offer*” in all controversial cases.

4.1.2. Distance

Referring to section 2, “distance” according to Kress and van Leeuwen can be encoded as intimate/personal, social or impersonal. For the coders intimate/personal distance can be defined as “close shot”, social distance as “medium shot”, impersonal as “long shot” (see Kress & van Leeuwen, 2006: 148). Below the results of “distance” coding by two Russian and two Indian coders are given. The whole photos’ corpus comprises 526 ($N_{ph} = 526$) items.

Figure 3. The meeting of the Patriarch with Naryshkin. Note: The Russians and the Indians encoded this photograph as “*demand*”.

Figure 4. The meeting of the Patriarch with the foreign delegation. Note: The Russians and the Indians encoded this photograph as “*demand*”.

Figure 5. During the Liturgy. Note: The Russians and the Indians encoded the given photographs differently: The Indians have chosen “*demand*”, while the Russians have chosen “*offer*”.

Figure 6. Meeting of the Patriarch with Naryshkin.

4.1.2.1. Overview of Inter-Rate Reliability (Cohen's Kappa κ ; Krippendorff's Alpha α)

The results of encoding are presented in Table 7. It is evident, the Cohen's Kappa agreement between two Indians is 0,941, that means substantial agreement ($p = 0,000$). It is needed to note that the level of agreement between Russians coders is either high ($\kappa = 0,968$). It means almost perfect agreement. By comparison, statistical significance is $p = 0,000$.

In contrast, the level of agreement between coders from India and between coders from Russia is rather low. For example, the Cohen's Kappa agreement between Russian 1 and Indian 1 is 0,599, between Russian 1 and Indian 2 is 0,632, between Russian 2 and Indian 1 is 0,608, while between Russian 2 and Indian 2 is 0,641. It is worth mentioning that the encoding of "*distance*" gives the highest level of Krippendorff's alpha agreement throughout the whole photos' corpus. Table 8 below shows the Krippendorff's alpha for distance system. Krippendorff's alpha has values from 0.776 (Krippendorff's alpha ordinal) to 0.788 (Krippendorff's alpha ratio). However, despite the Krippendorff's alpha is 0.776/0.788, this value is less than 0,800. Provided it is higher than 0.800, social scientists can rely on the data.

In general, respectively high level of general agreement does not lead to a complete lack of distinction. In comparison, Cohen's Kappa κ shows that agreement between the Indians is 0,941, between the Russians is 0,968 while between the Russians and the Indians it varies from 0,599 to 0,641. Thereby, the conclusion can be made that the system of *distance* shows little difference in coding between the Russians and the Indians.

4.1.2.2. Results of Distance Coding ($N_c = 4$; $N_{ph} = 526$)

Table 9 presents the results of distance coding. There is a tendency among the Indians to code most of the photos as intimate/personal, while the Russians put more emphasis on impersonal distance (see Table 9). Considering the coding as impersonal the difference reaches 13,1%-14,1% for the Indians and 22,2%-22,4% for the Russians. In contrast, the difference in intimate/personal coding is less and varies from 12.2% for the Indians to 9,5%-9,7% for the Russians. The difference might be detected because of the size of the photographs' corpus ($N_{ph} = 526$). Both groups encode the majority of photos as social distance at the same time (from 68.1% of Russians to 73,8-74,7% of Indians).

The photos with full consent and full divergence in coding have been chosen to illustrate slight disagreement with the Russians and the Indians "*distance*" coding. The physical distance in Figures 8 and 9 are measured as dissimilar, but the Indians and the Russians encoded it like identical.

Table 7. Result of Inter-rater reliability (Cohen's Kappa κ) for *Distance*

	Indian1	Indian2	Russian1	Russian2
Indian1	X	0,941	0,599	0,608
Indian2	0,941	X	0,632	0,641
Russian1	0,599	0,632	X	0,968
Russian2	0,608	0,641	0,968	X

Note: Green colour shows substantial and almost perfect agreement, red colour shows moderate agreement.

Table 8. Value of Krippendorff's alpha for the system of *Distance*

Krippendorff's alpha (ordinal)	0.776	N coders:	4
Krippendorff's alpha (interval)	0.779	N cases:	526
Krippendorff's alpha (ratio)	0.788	N decisions:	2104

Table 9. Results of the system of *Distance coding* (%)

	Indian 1	Indian 2	Russian 1	Russian 2
Intimate/personal	12,2	12,2	9,7	9,5
Social	74,7	73,8	68,1	68,1
Impersonal	13,1	14,1	22,2	22,4
Total	100	100	100	100

In the provided photos the Patriarch is seen in full length, at least the most part of his body is visible. The event where the Patriarch blesses parishioners does not distract from the adequate code description. For Russian coders this procedure tends to be rather controversial, only if they accept this religious event as personal (see Figures 8 and 9). In some cases they could evaluate the distance as “*intimate/personal*” in Figure 9.

Figure 8. The Patriarch is in front of the departed bishop. Note: Both the Russians and the Indians encoded the photograph as “*social distance*”.

Figure 8 explains why the coders refuse to code “*distance*” as “*intimate /personal*”, and justify their refusal. It is open to question why the distance in Figure 9 is not coded by the Russians as “*intimate/personal*”. During the coding of Figure 11 they perceive distance as more remote and evaluate it as the maximum “*impersonal distance*”. In contrast, the Indians encode this distance as the “*social*” (see Figure 11).

The Russians demonstrate consistency in the analysis and in most of the cases (more than 40 photos) consider the distance as a far location (see e.g., Figures 10 and 11). The situation indicates that the Russians comprehend the Patriarch as more distant than the Indians. The ambiguity creates uncertainty, whether Russian coders intend to distance themselves from the religion or quite the opposite: whether they get involved in religious life and, therefore, consider the Patriarch as a person who belongs to this world either. Nevertheless, the factors that influence their choice in controversial situations are still unknown. For example, the

Russians treat the Patriarch like a spiritual figure, the Indians on their part equals the Patriarch with an ordinary person (see Figure 9). The authors of this article evaluate the participants' attitudes and highlight the influence of ideology. In all circumstances, further research is recommended in order to get more accurate results.

Figure 9. The Patriarch blesses archimandrite before ordination in bishop. Note: Both the Russians and the Indians encoded the photograph as “social distance”.

Figure 10. Communication between the Patriarch and the future bishop. Note: The Russians and the Indians encoded the photograph differently: The Russians have chosen “social distance” and the Indians have chosen “intimate/personal distance”.

Figure 11. The Patriarch, two metropolitans and bishops of Orthodox Church. Note: The Russians and the Indians encoded the photograph differently: the Russians have chosen “impersonal distance” and the Indians have chosen “social distance”

4.1.3. Attitude: Involvement and Detachment

Section 2 allows us to indicate “attitude: involvement” as “frontal angle” while “attitude: detachment” can be indicated as “oblique angle” (see Kress and van Leeuwen, 2006: 148). In this sub-section, the results of coding “attitude” are given: “involvement and detachment”, conducted by two Russian and two Indian coders (the whole photos corpus equals to $N_{ph} = 526$, $N_c = 4$).

4.1.3.1. Overview of Inter-Rater Reliability (Cohen’s Kappa κ ; Krippendorff’s Alpha α)

The results of coding by two Russian and two Indian coders are presented in Table 10. Table 10 shows the value of measure of agreement Kappa that makes 0,924 between two Indians. Value 0,924 means substantial agreement. Calculation has either figure $p = 0,000$. It is needed to note that the level of agreement between Russian coders is also high ($\kappa = 0,954$), what means almost perfect agreement. At the same time the relationship is statistically significant ($p = 0,000$).

The level of agreement between coders from India and Russia is essentially low. Between Russian 1 and Indian 1 the value of measure of agreement Kappa is 0,296, between Russian 1 and Indian 2 the value of measure of agreement Kappa is 0,288, between Russian 2 and Indian 1 the value of measure of agreement Kappa is 0,292 and between Russian 2 and Indian 2 the value of measure of agreement Kappa is 0,283. Additional calculation of Krippendorff’s alpha α is conducted in order to insure that the degree of agreement in the encoding of “attitude: involvement and detachment” between members of international team is really low; data reliability is $\alpha = 0.491$ (see Table 11). In addition, there is a strong disagreement between the Russians and the Indians regarding the system of “attitude: involvement and detachment”.

Table 10. Result of Inter-rater reliability (Cohen's Kappa κ) for Attitude: Involvement and Detachment

	Indian 1	Indian 2	Russian 1	Russian 2
Indian 1	X	0,924	0,296	0,292
Indian 2	0,924	X	0,288	0,283
Russian 1	0,296	0,288	X	0,954
Russian 2	0,292	0,283	0,954	X

Table 11. Value of Krippendorff's alpha α for the system of Attitude: Involvement and Detachment

Krippendorff's alpha (ordinal)	0.491	N coders:	4
Krippendorff's alpha (interval)	0.491	N cases:	526
Krippendorff's alpha (ratio)	0.491	N decisions:	2104

Table 12. Results of encoding of the system of Attitude: Involvement and Detachment (%)

	Indian 1	Indian 2	Russian 1	Russian 2
Involvement	12,5	13,5	28,3	29,5
Detachment	87,5	86,5	71,7	70,5
Total	100	100	100	100

To sum up, the following section makes an attempt to reveal the reasons for the difference occurrence. The system of “attitude: involvement and detachment” points out the difference in agreement between the Russians and the Indians. The level of inter - rate reliability among the Indian coders is high (0,924). The same situation is true for the Russian coders (0,954). Overall, it can be seen that the level of inter - rate reliability among the group of Indian coders and among the group of Russians coder is quite high throughout the procedure of coding. However, the level of agreement between the Russians and the Indians is ranged from 0,288 to 0,296; Krippendorff's alpha α (ordinal, interval, ratio) has quite low value 0.491 with four coders.

In the case of “attitude system: involvement and detachment” demonstrate the highest level of differences and the lowest degree of agreement between Indian and Russian coders is demonstrated. Thus, the code system, developed by Kress and van Leeuwen as subjectivity involves measurement of subjective evaluation and attitude. Nevertheless, the description codes “*frontal angle*” and “*oblique angle*” clear up and simplify the encoding process.

4.1.3.2. Results of Coding of Attitude: Involvement and Detachment ($N_c = 4$; $N_{ph} = 526$)

The results of the system of “attitude analysis: involvement and detachment” are presented in table 12. Cohen's Kappa κ and Krippendorff's alpha α show that the cases, when both Russians coders chose other value than both Indians, are frequent. Table 12 and Figure 12 tell about the significant differences between the Russians and the Indians in the evaluation of “attitude: involvement and detachment”. According to both Indian and Russian

coders, “detachment” prevails in the full corpus of photographs. However, the Russians prefer “involvement” more often than the Indians. The Indians perceive the photographs angles as more detached. In general, both Russians coded 84 photos from the whole photos’ corpus as “involvement”, whereas both Indian coders have chosen “detachment”.

The selected photographs with complete agreement and significant disagreement between two groups of coders illustrate the differences. Figures 13 and 14 present the complete agreement between the Russians and the Indians in the coding of “*attitude: involvement and detachment*” in the provided photographs. Accurate description of “*oblique angle*” facilitate coding of photographs as “*detachment*”.

The apparent examples of “*attitude*” coding discrepancy: *involvement and detachment* photographs between the Russians and the Indians are the following (see Figure 15a). The Russians have chosen “*involvement*” while the Indians have chosen “*detachment*”. “*Detachment*” seems to be either true for Figure 15, where “*frontal angle*” is seen. However, the big icon in the centre can be taken for “*frontal angle*” (see Figure 15a). Russian coders were invited to give comments (see Section 4.2.).

4.1.4. Attitude: Viewer Power, Equality and Represented Participant Power

The study of interactional metafunction shows that (Section 2, Table 1) “*attitude: viewer power*” can be indicated as “*high angle*”, “*attitude: equality*” can be indicated as “*eye-level angle*” and “*attitude: represented participant power*” can be indicated as “*low angle*” (see Kress and van Leeuwen, 2006: 148). The following part of the paper presents the results of encoding “*attitude: viewer power, equality and represented participant power*” by two Russian and two Indian coders (the whole photos’ corpus $N_{ph} = 526$, $N_c = 4$).

Figure 13. The future bishop takes an oath in front of the Patriarch before ordination. Note: The Russians and the Indians encoded this photograph equally; they both have chosen “detachment”.

Figure 14. The Patriarch and bishops before ordination. Note: The Russians and the Indians encoded this photograph equally; they both have chosen “detachment”.

Figure 15a. The Patriarch's service in Cathedral of Christ the Savior in Moscow. Note: The photograph was encoded by the Russians and the Indians differently: The Russians have chosen “involvement” but the Indians have chosen “detachment”.

4.1.4.1. Overview of Inter-Rater Reliability (Cohen's Kappa κ ; Krippendorff's alpha α)

The results of encoding by two Russians and two Indians coders are presented in Table 13 below. The value of agreement Cohen's Kappa κ between two Indians is 0,873. It means substantial agreement with statistical significance $p = 0,000$. It is worth attention that the inter-rater reliability of the level of agreement between Russians coders is also high ($\kappa = 0,837$). It means almost perfect agreement, statistically significant ($p = 0,000$).

Table 13. Result of Inter-rate reliability (Cohen's Kappa κ) for Attitude: Viewer power, Equality and Represented participant power

	Indian 1	Indian 2	Russian 1	Russian 2
Indian 1	X	0,873	0,251	0,278
Indian 2	0,873	X	0,321	0,345
Russian 1	0,251	0,321	X	0,837
Russian 2	0,278	0,345	0,837	X

Table 14. Value of Krippendorff's alpha α for system of Attitude: Viewer power, Equality and Represented participant power

Krippendorff's alpha (ordinal)	0.5	N coders:	4
Krippendorff's alpha (interval)	0.54	N cases:	526
Krippendorff's alpha (ratio)	0.62	N decisions:	2104

In contrast, the value of measure of agreement Kappa between Russian 1 and Indian 1 is only 0,251, it makes 0,321 between Russian 1 and Indian 2, it is 0,278 between Russian 2 and Indian 1, while it is 0,345 between Russian 2 and Indian 2. The Krippendorff's alpha is also low ($\alpha < 0.667$) (see Table 14). There is a need to show significance of the study, so measure of agreement between two groups of coders is lesser than measure of agreement between coders of one group. It also took place in the previous measurements of inter-rater reliability in the coding of the systems of “*contact*” (See Section 4.1.1.), “*distance*” (See Section 4.1.2.) and “*attitude: involvement and detachment*” (See Section 4.1.2.). The emerged tendency remains steady throughout the research.

4.1.4.2. Results of Coding of Attitude: Viewer Power, Equality and Represented Participant Power ($N_c = 4$; $N_{ph} = 526$)

The results of the system of power analysis are given in Table 15. As it is shown in the table below (see Table 15) the differences in evaluation between two Russian and two Indian coders emerge only with regard to equality and representation power. As for power representation the same differences appear twice: The Indians coded 20,7-25,3% from the whole photos' corpus as “*representation power*”, while the Russians do the same for 47,1-47,4% of photos. According to the Indians the coding of 67,1-71,4% photographs are characterized by *equality*, but the Russians encoding mentions *equality* in reference to 44,6-45% of photographs. In the case of *viewer power*, there is no difference in encoding: 7.6-7.9% of the whole photos' corpus for Indian coders and 7.6-8.3% for Russian coders.

Table 15. Results of encoding of the system of Attitude: Viewer power, Equality and Represented participant power

	Indian 1	Indian 2	Russian 1	Russian 2
Viewer power	7,9	7,6	8,3	7,6
Equality	71,4	67,1	44,6	45
Representation power	20,7	25,3	47,1	47,4
Total	100,0	100,0	100,0	100,0

Figure 18. The Patriarch wears mitra during the Church service. Note: The Russians and the Indians encoded the photograph as “*represented participant power*”.

One of the essential distinctions in the perception of “*represented participant power*” has been revealed. Interpretation of “*represented participant power*” as “*low angle*” given to coders seems to be a bit confusing as it deals more with photo’s geometry than power. In order to comment on the mentioned episodes, the photographs with complete agreement and total difference in coding were selected. The Russians and the Indians demonstrate full agreement while encoding “*attitude: viewer power*”, “*equality*” and “*represented participant power*” in the following photographs (Figure 18 and 19).

The perfect examples of differentiation in encoding of power between two Russians and two Indians are provided below (see Figures 20, 21).

Figure 19. The Patriarch blesses laity using dikiri and trikiri. Note: The Russians and the Indians encoded the photograph as “*represented participant power*”.

Figure 20. The Patriarch's prayer. Note: The photograph was encoded by the Russians and the Indians differently: the Russians have chosen "*represented participant power*" while the Indians have chosen "*equality*".

The significant differences exist between the Russians and the Indians in the coding of "*attitude: viewer power, equality and represented participant power*". The Russians and the Indians evaluate "*viewer power*" similarly. However, in respect to "*equality*" and "*represented participant power*", their reports contain serious disagreement. Thus, the authors of this paper call the necessity in specifying the coders' position and feelings during the coding (see Section 4.2.).

Figure 21. The Patriarch in the Cathedral. Note: The photograph was encoded by the Russians and the Indians differently: the Russians have chosen "*represented participant power*", while the Indians have chosen "*equality*"

4.2. Stage II. Results of Semi-Structured Interview with Coders

The semi-structured interviews with four coders were conducted to reveal the problems arised during the coding process and answer the second research question that sounds: How did two Indian coders and two Russian coders overcome problems they encountered during the coding of the whole photos' corpus? Over the semi-structured interviews the Indian coders were questioned in English language, while the Russian coders communicate in Russian. As the result, socio-demographical characteristics of the coders are presented in Table 16.

Following the *guide of semi-structured interview* with coders, a set of open questions were asked. All the questions are related to the main problems, ideas or emotions during encoding.

Table 16. Socio-Demographical Characteristics of Coders

	Age	Gender	Job or profession	Religion	Time of coding
Indian 1	26	m	Student, the restaurant worker	Don't mention	A week
Indian 2	23	f	Student, the restaurant worker	Indian traditional	A week

Russian 2	23	f	Master student, part-time office-worker in an advertising agency	Don't mention	Five days

4.2.1. Common Problems of Coding

Actually, each coder reports some problems with coding. The common problems of coding reported by Indian coders are presented in Table 17. The considerable problems mentioned by the coders are as the following: *the lack of time, the difficulty of coding task and freakish photos* (see Table 17).

The lack of time and the difficulty of the task can be taken for granted while coding 526 photos' corpus. More than that, the Indians claim that the strangeness of photos can be justified by the character of cultural traditions. The photos of the Russian Patriarchs are culturally dependent and rooted in the Russian culture exclusively, consequently, the Indians may perceive them critically. The Orthodox Patriarchs' photos are not only unusual and odd for perception, but also can challenge Indian tradition. The latent negative attitude to Orthodox ideology appears because it does not match Indian culture and, as the result, are seen inadequate during the photo perception. It means that the Orthodox Patriarchs' photos are not considered like an image of someone or something but are reckoned as ideological. Moreover, a photographer probably did not anticipate how the photo ideology can be perceived. In the case of the Indian coders, this ideology is perceived quite negatively and influence Indian coders to work slower and without enthusiasm.

As for Russian coders, they also face problems (see Table 18). The most significant problems mentioned are: problems with the use of English, English-Russian translation, the link between the name and the description of codes and the usage of the inadequate Western theory for the current task. In addition, the following problems are mentioned by one of the

Russian coders: poor knowledge of SPSS, the difficulty with the task coding, gender inequality, lack of instructions for coding.

Table 17. Common problems of coding according to the Indian coders

	Problems	Transcript excerpts
Indian 1	time	To be honest...(pause) I did not have enough time to complete this task.
	task difficulty	This work was... really-really difficult for me.
	uncustomary photos	These photos probably look rather strange to people unfamiliar with the Patriarch, etc... It takes a lot of time ... to find him, to see... Here is a rather strange thing that look nothing like ... these photographs have nothing to do with the Indians...(pause)
Indian 2	time, task difficulty	Actually, I am studying in Medical Academy and at the same time I work in restaurant "Tandoor" in Saint Petersburg. So after work I come back home and feel very tired and it was needed to force myself to do this encoding ...to be honest during coding of some photos I could not find who the Patriarch is....among all these people. Then I called my friend and asked him. He told me that Patriarch dressed in green vestments.
	uncustomary photos, odd looking photos	I face no problems apart from the odd looking photos... Almost all of them are odd looking

It is obvious that Russian coders in comparison with Indians highlight plenty of problems, but only one problem marked as *the difficulty with coding* coincides with the Indians'. The problem *difficulty of the coding task* is mentioned only by one Russian coder and deals mostly with the SPSS programme but not with photos' coding. The vast majority of problems are focused on cultural differences in coding. The Russians do not distinguish accurately, whether these problems are related to the translation, or they are influenced by Western experience that is invalid for the Orthodox Patriarchs' photos analysis. To sum up, both Russian coders come to conclusion that the Kress and van Leeuwen's theory cannot be applied. This idea is absent in the answers of the Indian coders who call photos as inadequate and odd looking. Nevertheless, both groups of coders face problems while interpreting the notion "inadequacy".

Two groups offer their interpretations of "inadequacy". While Indian coders explain it as a wrong approach in the Patriarch' behavior and dominance (one Russian coder names dominance as "gender inequality"), Russian coders take "inadequacy" as a concept gap between the name and the code descriptions. The authors of this article claim absolutely different perception of the coding problems among coders. Presumably, the Russians concern about "*instructions were not enough for coding*" can partially explain the divergence of views. However, it is wrong to assume that more detailed and prolonged instructional period may guarantee clearness in evaluation. On the contrary, more differences in perception are emphasized at the early stage of the study.

4.2.2. Problems of Coding of Contact, Distance and Attitudes

After the description of the main problems, the coders were asked to give comments on each system of **coding contact**, **distance** and both **attitudes**. The results of the Indian coders are presented in Table 19.

Table 18. Common problems of coding according to the Russian coders

	Problems	Transcript excerpts
Russian 1	poor knowledge of SPSS	I have never heard of SPSS before. So it was rather difficult for me to use this program.
	task difficulty	Also..... honestly, it was very boring and monotonous
	problems with the use of English or English-Russian translation	I encoded in English, but at the same time there were many problems with these codes .. I find difficulties with translation some words into Russian... For example, what is “detachment”? It is the first time when I see this word. I translate it as a non-involvement. Why our encoding is in English when the photos are Russian?
	absence of the link between the name and description of the codes	All the code names are... very strange... It seems these codes does not fit their names. The codes’ names look incorrect.
	irrelevance of the Western theory for the current task	I can see that “demand” and “offer” are also ideological names, they are borrowed from the Western facial expressions study. In turn, the Western experience of facial expressions is based on the Western ideology, for example, the American positive thinking. However, for other countries “gaze at the viewer” cannot be combined with “demand”. It is the irrelevance of the Western theory without suitable alteration.
Russian 2	gender inequality	Some of the photographs depict the Patriarch and the women in a way that they look not equal. The Patriarch is always above the women. The Patriarch always initiates the main action. There aren’t any photographs where women are initiators of an action.
	poor instructions for coding	I think instructions have to focus on controversial situations. After our meeting and instructions, I think everything is ok. However, when I just start my coding, I have found many controversial situations that are difficult for clear evaluation. Instructions should be longer with many details.
	problems with the use of English or English-Russian translating	Here at once, problems with understanding and translation of these terms arise.
	absence of the link between the name and the description of codes	Although I coded in English, the link between the name and the description of the code cannot be understood. So I relied on the description of the code and tried to find some angles.
	irrelevance of the Western theory for the current task	It seemed that problems appeared because the Western theory was used as you told us before. So, this theory can’t be effectively applicable in Russia.

Both Indian coders don’t mention any problem with the coding of “*contact*”. At the same time, both face the problem with “*distance*” coding. The more Indian 2 attempts to describe the image of the Patriarch as amiable the more evident it leads to coding the distance as less, e.g., as “*intimate/personal*”. At the previous stage of the present research we have found that the Indians see “*distance*” as more near/proximal than the Russians (see Table 9). Thereafter the semi-structured interviews confirm this tendency.

Table 19. Problems of coding of *Contact*, *Distance* and *Attitude* by the Indian coders

	System	Transcript excerpt
Indian 1	contact	No problems
	distance	It was not easy to measure “social distance” in the photographs. Interpretation of “social distance” which was given by Kress and van Leeuwen was not clear for me. What I think is... that... “social distance” is not a physical distance between the photographer and participants, but “social distance” is connected with interaction between people presented in the photographs
	attitude: involvement and detachment	Almost all photographs of the Patriarch have oblique angles. A viewer is an observer of the events or actions on the participants part. A photographer hasn't aligned himself with the Patriarch. He is always on the side...(pause)
	attitude: viewer power, equality and represented participant power	In my opinion, the Patriarch is a common person..... For the faithful he is a religious leader. For me, he is just a man. I see the Patriarch in photographs as a person equal to me...
Indian 2	contact	“contact” was easy. What can be difficult in “offer–demand”?
	distance	If a person looks more attractive, the distance seems less
	attitude: involvement and detachment	I cannot remember any problem
	attitude: viewer power, equality and represented participant power	I do not believe that the Patriarch has special religious power. For instance, I can believe that Ganesh is more powerful than Christian God... Actually, if some person is higher than another person it does not mean that he is more powerful. There is the same situation with the Patriarch. Photographers often depict the Patriarch as a person high authority. It irritates me because he is also human like me...

Regarding “*attitude: involvement and detachment*”, one of the Indian coders confirms that the Indians find more photographs of the Patriarch with oblique angles: “*Almost all photographs of Patriarch has oblique angles*”. Compared to the results of encoding of the whole photos’ corpus (see Table 12), some differences in perceptions of “*oblique angles*” between the Indians and the Russians are evident. The Indians refuse to explain and state the problems considering them “as default”.

Regarding “*attitude: viewer power*”, “*equality*” and “*represented participant power*” the Indians unexpectedly begin to report about their relation to the power of the Patriarch, but not about the problems in coding, insisting that the Patriarch is an individual equal to them. As one of the Indians claims: “*The most important thing is how people interact with each other, and where these people are placed in the photograph. I was very dissatisfied when the Patriarch’s face always takes the central position in the photos. The Patriarch for me is the same person like other people. Why is he always placed in the centre? Why does he often look taller than other people? I do not understand is it really needed to make a focus on one person*”. This saying determines the main reason why the reported results on power perception of encoding of the whole photos’ corpus (see Table 15) between Indians and Russians differs significantly. Despite the fact that both Indian and Russian coders are totally engaged with codes description, the eccentric reaction of Indians can be taken for the indirect evidence that coders also consider the meaning of the names of the codes (e.g., *Power*), the same is true for the Russians. The results for Russian coders are presented in Table 20.

Table 20. Problems of coding of *Contact*, *Distance* and *Attitudes* by the Russian coders

	System	Transcript excerpt
Russian 1	Contact	It seems that these codes do not match their names. If I looked at the code's name such as "<i>offer</i>" or "<i>demand</i>" I would have made inaccurate encoding. Therefore, controversies were decided with the second coder after looking at the description. The code names look incorrect. If the Patriarch does not see photographs, it does not mean that he demands something. He is being used of God and people who are present in Church. Even such word as "<i>offer</i>" is better than "<i>demand</i>" because "<i>offer</i>" of faith and service is the thing which Orthodox Church really gives to people. So, "<i>offer</i>" is more good characteristics of the Patriarch's behavior and all Orthodox Church ...we have a choice: we can see the description and we can see the name of the code. If we should choose the description, for example, "<i>gaze at the viewer</i>", then we should use a wrong nomination "<i>demand</i>". I can see that "<i>demand</i>" and "<i>offer</i>" are also too ideological names, they based on the Western facial expressions. In turn, the Western experience of facial expressions based on the Western ideology, for example, the American positive thinking. However, for other countries "<i>gaze at the viewer</i>" cannot combine with "<i>demand</i>".
	Distance	I cannot understand why " <i>social distance</i> " was written twice as the common name of all group and as a particular name of " <i>medium shot</i> ".
	Attitude: Involvement and Detachment	I think some words can't be translated into Russian... For example, what is "<i>detachment</i>"? It is the first time when I can see this word. I understood it as a non-involvement. I feel "<i>involvement</i>" in Liturgical actions which are often present in the photographs. I like to participate in Liturgical prayer. When I see these photographs I have the intention to pray. So for me, "<i>involvement</i>" does not connect with the angles. It is connected with situation and action which can be more interesting for me.
	Attitude. Viewer power, Equality and Represented participant power	The Patriarch for me is not just a person. He is the leader of the Church; he is responsible for all Orthodox Christians in Russia. The photographs often depict the Patriarch as a lovable father. And I agree with it... A lot of photographs were knowledge oriented. Even the depiction of the Patriarch's presence during the Liturgy is the source of knowledge about Liturgy.
Russian 2	Contact	The same problem arises with " <i>offer</i> " and " <i>demand</i> " because there is requirement with gaze
	Distance	(don't say)
	Attitude: Involvement and Detachment	Church photographers does not like to use frontal angles because during Liturgy they can't stay in front of the Patriarch. It is forbidden in Orthodox Church to stay between a priest or a bishop and an altar. So, they make photographs according to the church rules and regulations...I don't fully understand this division between "<i>involvement</i>" and "<i>detachment</i>". How can front angle be connected with "<i>involvement</i>"? "<i>Involvement</i>" for me means the participation in the process, but I can feel myself as a participant of the process depicted in photos without the frontal angle. The frontal angle does not give new information. Always the Patriarch should be in the center... Why? For example, I noticed a large icon in the center of the Church (Note: see Figure 15a).
	Attitude. Viewer power, Equality and Represented participant power	The power of the Patriarch is not actually his power. It is a spiritual power which is given from God. The photographs can't reflect this spiritual power. However, photographer can try to depict the Patriarch not as a bearer of some administrative resource but as a bearer of the grace of God. Some of the photographs are successful, in this regard.

The Russian coder 1 might treat coding too emotional; he always evaluates the procedure as “inappropriate” tool as the rational coding violates some important ideological items. Throughout the interview, he expresses a deep concern which means that he considers the Patriarch photos as ideology. At the same time he, in the line with the other coders, confirmed that the description from Table 1 is weighty for his coding.

Regarding the system of “*contact*”, both Russian coders have always confused codes “*offer/demand*” and interpret them more subjectively than stated in the description “*for other countries gaze at the viewer cannot combine with demand*” (Russian 1). Moreover, they evaluate the names of the codes “*offer*” and “*demand*” as more or less positive. For instance, the coder Russian 1 says “So, “*offer*” is more good characteristics of Patriarch’s behavior and the Orthodox Church”. Despite their belief that the coding is based on the description, a certain influence of cultural attitude can be seen in Table 6. “Results of coding of Contact”. It is evident that the Russian coders prefer “*offer*” more often than the Indians. The authors of this paper recognize it as cultural difference in perceptions of both the photos and the system of coding.

In contrast, regarding the system of “*distance*”, both Russian coders do not find any serious problems, while Indians are puzzled by non-attractive Patriarch’s view that leads to its perception as more distant. At the same time, regarding the system of “*attitude: involvement and detachment*” both Russian coders find problems similar with *contact*. In this case, they are discouraged by the word “*involvement*” and insist that involvement cannot be associated with “*frontal angle*”: “*How can front angle be connected with involvement*” (Russian 2). Finally, Table 12 shows “Results of encoding of the system of Attitude: Involvement and Detachment”, despite the Russians’ assumption that it has no influence on their coding.

Regarding the system of “*attitude: viewer power, equality and represented participant power*”, the situation differs but slightly from the Indians. The Russians mention Patriarch’s Power however, they do not take the Patriarch for an average person. The coding of “*attitude: viewer power, equality and represented participant power*” states drastic controversy between the Indians and the Russians (see Table 15). Russian coders perceive the Patriarch as the bearer of spiritual authority, while the Indians consider him as equal.

The above said confirms the influence of ideology on the perception of the photographs in different cultures exists. All coders, involved in the study, position themselves as ideologically neutral. However, a significant impact of the Orthodox ideology on Russian participants is evident. The Russians express more understanding towards the Church rules than the Indians and retain it during encoding. Over the interview the Russians associate themselves as action participants depicted in the photographs. The Indians take the Patriarch as an ordinary person; however, the image of Ganesh causes unconscious comparison of the Russian religious photos with the Indian religious photos. According to Russian’s point of view, the photographs depict the Patriarch as the “father” of an Orthodox believer.

In fact, both groups, the Indians and the Russians, constantly appeals to the domestic culture and cannot make coding without it. Despite their efforts to be objective and follow the instructions of the coding, they represent their cultural and ideological differences.

DISCUSSION AND CONCLUSION

The analysis is based on the issue whether it is possible to avoid the impact of cultural/ideological differences in coding when the ideal system of codes is provided, that enable to measure eye position or angle using computer program. The obtained answer is positive, but the authors cannot ignore the perception of free viewers which are not under control of the code book and the computer program.

Culture and ideology influence photo perception that is vital for photo producers. The role of the photograph in cultural/ideological/political affairs is likely to grow because of the increased importance of the internet, TV, 3D, virtual environment. Competing with video streaming, photographs still play a foundational role in communication process, however, little is still known about viewer's perception. This research tries to expand the understanding of photograph's role by focusing on how interactive meaning of photograph's is created, processed and interpreted by the representatives from non-Western cultures.

This study points out the importance of the Kress and van Leeuwen "visual grammar" in studying interactive meanings in photograph's. The authors of this paper share the view that the social semiotics' approach applied to the analysis of different forms of cultural communication allows to explore less known aspects of the very influential cultural/ideological institutions which "symbolic" power is depended on the use of visuals.

At the same time the problems faced during this research supply new ideas for the further understanding of cultural differences. Kress and van Leeuwen repeatedly focus our attention on the limitations of their theory based on Western examples (see e.g., Kress and van Leeuwen, 2006: 148). Despite this, the present study applies the theory in non-Western environment. It can be justified, firstly, by the need in tools for comparing different cultures, and secondly, to reveal and measure similarities that exist between cultures. So, this section highlights similarities and then proceeds to differences.

Similarities in the Russian and Indian perceptions of the Patriarch photographs' are explained by utilizing geometrical proportions. Russian and Indian perceptions of geometrical angles and distance are almost similar. Its worthiness opens possibilities for the expanded research based on the Kress and van Leeuwen theory. In the present research, all problems with interpretation of angles and distance are connected with ideological/cultural reasons and requests that results from interpretations. However, ideological/cultural reasons exist and their influence on the outcome of the research is rather strong. First challenge deals with the names of Contact's codes that are "demand" and "offer".

In spite of the fact that both Russia and India are non-Western countries, it is wrong to think that they are the same. From this point of view, the term "non-Western" calls something unknown, hidden from the Western analytical sight, a demarcation of white spot on the map of consciousness, than it is an explanation of something that is really "non-Western". For example, our Russian and Indian coders and respondents employ different strategy in coding/evaluating of "demand" and "offer". Surprisingly the Indians shows understanding of "demand" with slight similarity to "Western" as it is described in the Kress and van Leeuwen theory. At the same time, the Russians consider "demand" as a problem as it can not be clearly described geometrically. "Demand" and "offer" for Russians are different types of behavior when "demand" is a strong request "offer" expresses a soft request.

Coming back to offer/demand problem the question is stated whether Russian understand offer/demand wrongly. Halliday describes “demanding” as: *questions (ask, demand, inquire, query) or commands (call, order, request, tell, propose, decide; urge* (‘command: persuasive’), *plead* (‘command: desperate’), *warn* (‘command: undesirable consequences’)) (Halliday & Matthiessen, 2014: 514). Only part of these meanings of “demanding” can be understood in Russia correctly. Russians can understand “demanding” as *commands*. Most part of the commands’ meaning is acceptable for the Russians. However, the interpretation of “*plead*” (‘command: desperate’) also carries the meaning “offer” either.

The meaning of “demanding” as *request* is polysemnatic. For example, a teacher can apply to students with “demand” and a police officer can apply to humans with “demand”, but they should confer power to perform like this. It means Russian “demanding” (“trebovanie”) is tightly connected with the hierarchy and the power. From this point of view, for instance, the President of the United States cannot command to the Russians. It cannot be possible and “demand” cannot be accepted in any case without any dependency of eye position or angle.

Looking through the Patriarch photos the following paradox is seen. While the Indians code the Patriarch photos as “demand”, the Russians place a refusal. Suppose it happens because the Indians employ the exact meaning of “demand” in English, whereas the Russians rely on its literal translation into Russian as a “requirement” - “trebovanie”. The Russians explain the ignorance in coding “demand”/“trebovanie” as the power of the Patriarch spreads in the other dimension. It means that the Patriarch has the sacral power, thus, evaluation his actions as administrative power is unacceptable. Therefore, the Russians’ interpretation of “demand” means not abstract power, but an administrative power. As the result, the Russians code/evaluate the Patriarch actions as “offer”. For example, one of the Russian coders (Russian 2) notes: “*Power of Patriarch is not actually his power. It is a spiritual power which is given from God*”. So, van Leeuwen’s concept: “They do not look at the camera and therefore there is no social interaction with the reader” (van Leeuwen, 2008: 141) is not applicable here. The Patriarch does not look in the camera, however he actively interacts with Russian viewers who follow Orthodox ideological traditions.

The influence of ideology is found in coding/evaluation of “distance” and “attitudes”. Regarding system of “distance” the Indians and the Russians have contradiction in evaluation “more personal”/“more impersonal” distance. While Indians evaluate the Patriarch as an ordinary person and tend to “more personal” distance, the Russians treat the Patriarch as a spiritual person and, as a result, evaluate distance as impersonal because they do not count the Patriarch as an entity of the real world.

Regarding the system of “attitude: involvement and detachment” Indians and Russians experience contradiction around the term “part-whole relations”. “Involvement” is considered like part-whole relation (see e.g., Halliday & Matthiessen, 2014: 295). The results say that the Indians try to exclude themselves from the religion process depicted in the Patriarch’s photos and prefer “detachment” if the situation is controversial. Whereas the Russians are fully engaged with the church actions and chose “involvement”: “*I feel involved in Liturgical actions which are often presented in the photographs*”. In addition, some Russian coders fail to understand the meaning of the word “detachment”, it is witnessed in the saying: “*For example, what is “detachment”? It is the first time when I see this word. I understood it as a non-Involvement. Why our encoding was in English when they are our Russian photos?*”. This ideological and linguistic divergence lead to the significant differences in the photos’ evaluation as “involvement” or “detachment”.

Regarding the system of “attitude: viewer power, equality and represented participant power” Indians and Russians are faced with different interpretations of equality and represent participant power. The situation is almost similar to the “distance” evaluation/coding. Based on the vision of Patriarch as an ordinary person the Indians try to evaluate photos as “equality”, while the Russians prefer to see “represented participant power”. The Russians vision of “represented participant power” has a weak focus on Kress recommendations of angle because power for the Russians can be represented from both angles: high and low. Moreover, visualization from a high angle can represent the Patriarch as a “lake” where people may float to as streams down the mountains.

Thus, throughout the research both Indian and Russian coders and respondents have attempted to introduce their opinions about the photos orally, however, they come across problems like the choice of appropriate linguistic tools to describe visual phenomena. On the one hand, photos of different cultures cannot be described/compared non verbally, on the other, words and their equivalents in different languages can lead to the “wrong”/ peripheral/unusual interpretation and processing. In this research evaluation of the problems as culturally and ideologically determined is accepted. So, it is believed that words make ideology transparent as shown in the examples where the Russian is influenced by the Orthodox ideology and the Indian attempts to reconfigure the ideology according to Indian traditions. The Russians and the Indians do not provide unanimous opinions throughout all the codes. All codes are characterized by discrepancies in opinions of the Russians and the Indians. The angle geometry allows us to identify similarities in coding, but little is said about the photos’ perception. All the other cases of photo interpretation are strongly influenced by the ideology.

Chapter 19

**MULTIPLE TYPES OF “THE GOOD” IN HRYHORII
SKOVORODA’S PHILOSOPHICAL DISCOURSE:
*DOBRO VS BLAHO***

Larysa M. Dovga*

Cultural Studies Department, National University of “The Kyiv-Mohyla Academy”,
Kyiv, Ukraine

ABSTRACT

This chapter is dedicated to the formation of philosophical terminology in the history of Early-Modern Ukrainian culture. Two philosophical concepts—*dobro* and *blaho* (добро and благо)—are the focus here. Both are related to notions of good and wellbeing, but contextual nuances may affect their discrete meanings rather significantly. My main goal is to track the differences between them and discover the rationale behind them. I consider the manner in which these two words functioned in the works by the prominent 18th century Ukrainian philosopher Hryhorii Skovoroda. My study is based on a close reading of thirteen of his colloquies. In the process, I have also tackled the problem of translation posed by these complicated terms.

My study has led to the following conclusions: 1) Skovoroda uses the word *blaho* when discoursing about the Creator, the Sacral World, and reflections of the sacral in profane human life. In such contexts he uses *blaho* as a philosophical concept. 2) Skovoroda reserves the term *dobro* for the profane sphere, while describing things that are positive from a moral point of view. In such cases, the semantic field of the word is clearly defined, though it can hardly be called a philosophical term. 3) The common, conversational application of *dobro* does not have clearly defined boundaries and as such it does not represent a discrete concept. 4) When translating Skovoroda’s works into other languages, it is desirable to select the closest equivalents of each term. For example, the Greek κάλλος (τὸ κάλλον) or τὸ εὖ and the English *Everyday Good* are good analogs for *dobro*. On the other hand, the Greek τὸ ἀγαθόν and the English *The Highest Good* or *The Ultimate Good* closely render *blaho*.

Keywords: *dobro*, *blaho*, lexeme, terms, philosophical concept, early-modern Ukrainian language, Hryhorii Skovoroda

INTRODUCTION

Research into the formation processes of a language's conceptual apparatus is productive and useful for many scholarly disciplines, such as the history of language and culture, as well as historical anthropology. It is especially fruitful in the study of philosophical thought. An understanding of how semantic fields, as well as individual words, terms and concepts were formed helps scholars in the reading of ancient texts. Such an understanding is essential for translators of historical sources who need to capture semantic nuances and relate the original to modern audiences without perverting the meaning of the original.

This chapter is dedicated to the problem of formation of Ukrainian philosophical terminology in the Early-Modern period. The main focus is on the difference between two nouns, conveying two different notions of “the good”: *dobro* and *blaho*. In contemporary everyday speech these two words function as synonyms, but in philosophical and theological tracts each one is a discrete term with its own specific context and rules of usage. To complicate matters, most modern European languages, as well as their learned predecessor—Latin—have only one word for both terms: *bonum* in Latin; the good in English; *gut* in German; *dobro* in Polish, and so on¹. This complicates the translation of Ukrainian philosophical texts. Rendering both *dobro* and *blaho* as *bonum*, *the good*, *gut*, *dobro*, etc., erases the semantic difference between the two and produces an inaccurate translation. This is especially true of texts that rely on the play of words highlighting the distinction between these two as separate phenomena.²

The formation of Ukrainian philosophical terminology in the Early-Modern period was greatly influenced by Old Church Slavonic, Greek, Latin, and Polish. Among these, only Greek and Old Church Slavonic have multiple names for the phenomena, which are designated as *dobro* or *blaho* in Old Ukrainian, as well as modern Ukrainian. In Greek they are τὸ ἀγαθὸν, τὸ κάλλος, τὸ χρηστὸν, τὸ εὖ, ἡ ὥρα. In Old Church Slavonic they are *doŭro* and *blaŭzo*. This allows us to assume that the intellectuals of the Kyivan Metropolitanate³ saw the need to distinguish between *dobro* and *blaho* and to separate their semantic fields from the ancient traditions of Eastern Roman theology. The fact that these old Byzantine roots were still present in their language in Early Modernity suggests that at the initial stages of its formation (till the middle of 17th century at least) Ukrainian theological and philosophical thought was under the considerable impact of Greek tradition. Therefore, despite the palpable dominance of Latin influences on Old Ukrainian traditions of philosophical writing, the Greek factor should not be neglected. The texts written by Hryhorii Skovoroda in the second

¹ Exceptions here are Greek and Russian. In Greek there are five terms that may be used in similar ways: τὸ ἀγαθὸν, τὸ χρηστὸν, τὸ εὖ, τὸ κάλλος, ἡ ὥρα. Russian uses the same words – *dobro* and *blago* – but their semantic fields slightly differs from those of Ukrainian equivalents.

² This is exactly what happened in otherwise high quality English translations of works by Hryhorii Skovoroda. Further in this chapter I am going to analyze one of these translations.

³ I use the term Kyiv Metropolitanate in reference to the Ruthenian lands of the Polish-Lithuanian Commonwealth within their boundaries in the 16th and 17th centuries. These territories were slightly more expansive than the modern Ukrainian state.

half of the 18th century support this view. His language is a very unique and harmonious admixture of Old Ukrainian, Old Church Slavonic and Russian. However, when he needs to further dissect (in his own words, “to chew at the meaning” of) some difficult concepts, Skovoroda turns to either Latin or Greek, organically intertwining them in his texts.

HISTORIOGRAPHY

A rigorous study of any philosophical theory or the views of any thinker needs a detailed analysis of word-usage in the relevant texts. This is a time-honored approach and I need not expound my methodology in detail. Here, I would rather focus on preceding research on scholarly language formation in Early-Modern Ukraine. Let me first note a recent successful project directed by Barbara Cassin, titled *Dictionary of Untranslatables. A Philosophical Lexicon* [Cassin, 2004]. This is one of the grand projects in the field of semantics that deals with the formation and usage of philosophical terms in multiple European languages. This work, especially in its Ukrainian redaction, informs my methodological approach and is a great source of factual information. In her Introduction, Barbara Cassin states that the language problem poses one of the prime challenges for European scholars in the humanities. This is not only a theoretical issue, but also a practical one. Mutual understanding is one of the key factors in any communication. But how do we achieve this understanding when our philosophic lexicons are so diverse? Maybe, it is possible to find one dominant language in this inter-lingual polyphony, something akin to Latin in earlier times? But this is hardly possible in a world where the pluralism of cultures, thought and manner of thinking is a preeminent value. Instead, Barbara Cassin proposes translation as a mechanism of agreement among the philosophical languages of different nations. However, since a direct literal translation does not work in every case because of the peculiarities of each individual language structure, scholars often have to work on finding the best interpretation of the original, rather than its closest equivalent. Such a task demands a specific manner of treating the philosophical text, one that would allow the study of semantic fields for every single word in every single language.

Significantly, Cassin’s project, originally realized in French, today has already been translated (or is being translated) into English, Arabic, Spanish, Portuguese, Romanian, Persian and Ukrainian. Each of these new editions represents a research project on its own, each one broadening the original version by adding more and more new source languages, new synonyms and different equivalents for many terms, etc. For this chapter, I have relied on the Ukrainian redaction of the *Dictionary*, edited by Kostiantyn Sihov and Andrii Vasylychenko [Cassin & Sihov, 2009]. While working on the Ukrainian version, the authors not only searched for the best way to adapt “European philosophy” by the Ukrainian linguistic apparatus, they also conducted an analysis of their native intellectual tradition. As a result, they are preparing an additional fifth volume, which will be fully dedicated to Ukrainian philosophical language. The question of semantic differences between *dobro* and *blaho* will be covered there in a special article.⁴

⁴ The fifth volume of the Ukrainian edition titled *Slovnyk ievropeiskykh filosofii: leksykon neperekladnostei* [Dictionary of Ukrainian Philosophy: Lexicon of the Untranslatable] is to be published in 2018.

Sihov's and Vasyl'chenko's large project is only the first specialized work in this field. Such questions as the history of philosophical terminology and its formation, the semantics of certain concepts, terms, notions in Old Ukrainian, and history of their development are all still considered marginal by Ukrainian historians of philosophy. This despite the fact that today Western scholars are pursuing such topics. Fortunately, there are many Ukrainian scholars in cultural, linguistic and historical studies, who are seriously interested in analyzing the semantics of specific terms and concepts within multiple disciplines, including philosophy. The results of their research are worth mentioning here. For instance, there is Hanna Dydyk-Meush' and Olena Slobodziauk's interesting linguistic study of Old Ukrainian scholarly vocabulary, titled *Ukrainian Landscapes of the 17th -18th centuries: Word, Text, Vocabulary* [Dydyk-Meush, 2005]. This work provides a detailed analysis of Old Ukrainian words used to describe different natural objects and landscape elements. The authors emphasize the fact that many homonyms, used in both old and modern Ukrainian, significantly differ in meaning. Therefore, such words have to be treated with special care when found in Early-Modern sources.

Then, there are concepts connected to some definite values, which have been thoroughly studied, because they are still widely used in historical, cultural and political debates. These are *Otchyzna*, an Early-Modern term that roughly corresponds to Latin *patria* and modern Ukrainian *Bat'kivshchyna* or *Vitchyzna*. Then, there are the modern proper names for Ukraine and Ukrainians (*Ukraina* and *ukraïntsi*). There are a number of interesting studies dedicated to semantic fields that could work for these terms in Early-Modern Ukrainian political discourse. Their authors include: Serhii Bahro [Bahro, 2015]; Larysa Dovga [Dovga, 2012]; Natalia Iakovenko [Iakovenko 2009, Iakovenko 2012]; Maksym Iaremenko [Iaremenko, 2012]; Zenon Kohut [Kohut, 2004]; Serhii Plokhii [Plokhii, 2005; Plokhii, 2006]; Frank Sysyn [Sysyn, 2006]; Tetiana Taiirova-Iakovleva [Taiirova-Iakovleva, 2013].⁵ Along with the aforementioned work by Dydyk-Meush and Slobodziauk, these texts clearly illustrate how the sense of certain terms could change in time and how radically it can differ from the modern one. For example, *otchyzna* was initially a term designating a land or property gained through inheritance; later it entered the political context with a noticeable shift in meaning; and only since the middle of 17th century it became constantly used in reference to the Hetmanate, i.e., the Early-Modern Ukrainian State.

In a number of studies on the history of ideas in Early Modernity the same analytical methodology was applied to analyze terms from the moral sphere, such as *chest'* (honor), *sumlinnia* (conscience), *shchastia* (happiness), *virnist'/zrada* (loyalty/betrayal), *chesnota/provyna* (virtue/ fault), *hrikh/tsnota* (sin/purity), *znannia/prostota* (wisdom/simplicity), etc.⁶ [Bondarevs'ka, 2005; Dovga, 2012; Korzo, 1999; Spivak, 2016; Zema, 1997; and others]. In these works the authors show that the meaning of the given words, as well as the sense and connotation of the concepts behind them, depended on several key factors. In addition to the time frame when a certain text was composed, these scholars also pay special attention to its function as a possible factor in semantic change. The most important part of the investigations concerning such terms as *Otchyzna*, *Chest'*, *Znannia*, *Svoboda* considers the manner in which semantic changes correlate with shifts in the mentality of the Ukrainian elite in the 17th and

⁵ For a detailed historiography of this topic see: [Bahro, 2013].

⁶ The English terms used here and further as equivalents of the Ukrainian originals are inexact and highly dependent on the context.

18th centuries. My own work includes studies about the semantic fields of the terms *dobro* and *blaho* as they were used in theological texts published in the Kyiv Metropolitanate during 17th century [Dovga, 2016a; Dovga, 2016b; Dovga & Olishchuk, 2016].

Before turning to the results of my own studies, I should present a historiography of Hryhorii Skovoroda and his writings. The scholarship devoted to his biography and intellectual legacy is really impressive. His works have been the focus of scholars, writers and journalists for more than 200 years now, and the list of all studies dedicated to him constitute a voluminous tome [Ushkalov, 2002]. I will only mention the literature that directly informed the making of this chapter⁷. The most important items here are the monographs by Maria Grazia Bartolini [Bartolini, 2010; Bartolini 2015], Karen L. Black [Black, 1994], Dmytro Chyzhevs’kyi [Chyzhevs’kyi, 2003], Lidia Hnatiuk [Hnatiuk, 2010], Oleksa Myshanych [Myshanych, 1994], George Y. Shevelov [Shevelov, 1994], Bohdan Strumins’kyi [Strumins’kyi, 1994] and Leonid Ushkalov [Ushkalov, 2007]. All of them address Skovoroda’s use of language. Although these works are rather general and the authors do not go deeply into the details of certain cases, they pose a number of interesting questions: How did this Ukrainian intellectual experiment with vocabulary? Why did he sometimes neglect the “purity” of his own language and mix it with Old Church Slavonic and even some peculiar Russian choices [Shevelov, 1994, p. 129]? What was the purpose of using several different ways to write a single word? Did Skovoroda give the shape of the word a meaning equal to its sense?

Each Skovoroda text has multiple layers of meaning. It conceals numerous secret senses that can be understood and interpreted in a myriad of ways. His colloquies are usually based on a dichotomy of terms, on the contrast between different senses conveyed in the same word and the diverse images associated with them. His interlocutors aim for the Truth as an ultimate value, but their ways of finding and realizing this Truth is based on different concepts. In some cases, all these diverse paths lead to finding a single word, the Right Word that would fully cover the meaning of the whole moral lesson, which is the object of the colloquy. This Right Word, as a real treasure, can only appear in the very end of the text. Thus, to understand the author’s message, the reader has to identify it clearly and get its meaning properly. There are numerous investigations in the fields of philosophy, cultural studies, history and theology, aimed at finding these treasures and decoding the messages of Skovoroda’s writings. Among the authors, I should name Maria Grazia Bartolini [Bartolini, 2014; Bartolini, 2017]; Iryna Bondarevs’ka [Bondarevs’ka, 2005]; Hryhorii Bilaniuk [Bilaniuk, 1994]; Dmytro Chyzhevs’kyi [Chyzhevs’kyi, 2003]; Archbishop Ihor Isichenko [Isichenko, 2013]; Georg Kline [Kline, 1994; Kline 1997]; Myroslav Popovych [Popovych, 2008]; Natalia Pylypiuk [Pylypiuk, 1990]; Olena Syrtsova [Syrtsova, 2014]; Leonid Ushkalov [Ushkalov, 2001], and Taras Zakydal’s’kyi [Zakydal’s’kyi, 1965]. Without their general works my analysis of certain individual terms would simply lose its point.

Finally, I have to mention two main source publications, which have made my research more feasible, namely *The Complete Academic Collection of Hryhorii Skovoroda’s Writings*, edited by Leonid Ushkalov [Skovoroda, 2011] and *Online Concordance to the Complete Works of Hryhorii Skovoroda* [Pylypiuk, 2008], created by Natalia Pylypiuk, Oleh Ilnytzkyj and Serhiy Kozakov as an analytical tool to the texts within the *Collection*. This last study

⁷ For further reading I recommend two historiographical works: [Bartolini, 2009; Dobko, 2007].

makes all the nuances and variations of Skovoroda's linguistic games available for a detailed scholarly investigation.

PRIMARY SOURCES

I have analyzed the following thirteen works, as they appear in the aforementioned *Online Concordance to the Complete Works of Hryhorii Skovoroda* (Pylypiuk, 2008) and *The Complete Academic Collection of Hryhorii Skovoroda's Writings* [Skovoroda, 2011]:

- *Besida 1, narechennaia Observatorium*. [Conversation 1]
- *Besida 2, narechennaia Observatorium. Specula. Ievreisky: Sion*. [Conversation 2]
- *Besida, narechennaia Dvoie: o tom, cho Blazhennym byt' lehko*. [Conversation The Two]
- *Blahodarnyi Erodii*. [Herodius]
- *Bran' archystratyha Mykhaila so Satanoi u sem: lehko byt' blahym. Borba i pria o tom: Pretrydno byt' zlym, lehko byt' blahym*. [Dispute]
- *Dialoh, ili Razhlahol o drevnem myri*. [Dialog or Discourse]
- *Dialoh. Imia emu: Potop Zmiiin*. [The Serpent's Flood]
- *Knyzhechka Plutarkhova o spokoistvyi dushy*. [Plutarch]
- *Knyzhechka o chtenyi sviashchen(naho) pysaniia, narechenna Zhena Lotova*. [Lot's wife]
- *Knyzhechka, nazyvaiemaia Silenus Alcibiadis, syrigh Ikona Alkiviadskaia*. [Alcibiades Icon]
- *Kol'tso. Druzheskii razhovor o dushevnom myri*. [The Circle]
- *Narkiss. Razhlahol o tom: Uznai sebe*. [Narcissus]
- *Razhovor piaty putnykov o istynnom shchastyi v zhyzni* [A Conversation]

To provide a more general historical overview of the semantic fields of the concepts *dobro* and *blaho* I also studied the language of several other 17th century texts published in the Kyiv Metropolitanate. All of these texts appeared in Old Ukrainian or Old Church Slavonic, although some of them represent translations from other languages:

- *Likarstvo na ospalyi umysl cholovichyi...* (Ostrih, 1607). [Anonymous, 1607]
- *Dioptra* (Vievis, 1612). [Anonymous, 1612]
- *Homilies on all Epistles of St. Paul the Apostle* (Kyiv, 1623) and *Homilies on the Acts of the Apostles* (Kyiv, 1624) by John Chrysostom [Chrysostom, 1623; Chrysostom, 1624]
- *Commentary on the Apocalypse* (Kyiv, 1625) by Andreas of Caesarea [Andreas of Caesarea, 1625]
- *A Slavonic-Ruthenian Lexicon and Explanation of Proper Names* by Pamvo Berynda (Kyiv, 1627) [Berynda, 1627]

- *Myr z Bohom choloviku* by Innokentii Gizel’ (Kyiv, 1669) [Gizel’, 1669]
- and a collection of sermons by Antonii Radyvylovskiy, titled *Vinets’ Khrystov* (Kyiv, 1688) [Radyvylovskiy, 1688]

OBJECTIVE AND METHODOLOGY OF THIS STUDY

This chapter endeavors to determine with maximum possible precision the semantic fields of the terms *dobro* and *blaho* as they are used in Hryhorii Skovoroda’s philosophical works. My goal is to help researchers address important practical problems that arise when interpreting and translating the legacy of this prominent Ukrainian author.

Primarily, I wish to develop a method that is applicable when approaching and interpreting Skovoroda’s writings on a micro level. This method should lead from understanding specific words to determining the meaning of certain phrases and, consequently, clarifying the message of entire texts.⁸ This approach coincides with one of the main approaches of Skovoroda, who himself analyzes many texts. He once proposed a treasure will not be found externally, but rather internally, within the Self.

My work follows on the footsteps of the microanalyses, conducted by many preceding scholars, who have:

- (a) identified the sources of Skovoroda’s writings, his inspiration, and the factors that influenced his general views;
- (b) identified the quotes in his texts, both direct and concealed, as well as the analogs he might have found in the mystical, philosophical and theological traditions of Western Europe, and
- (c) conducted detailed analyses and interpretation of discrete topics, motives and symbols that appear in his works.

My attempt at deconstructing the concealed meanings of Skovoroda’s texts “from below,” through individual word analyses will not replace the methodologies that are being used in this field. But I do believe that it represents a new and useful, supplementary point of view.

Let me outline the main stages of my work, which have led to the proposed conclusions:

1. I began with statistical calculations, by looking through the thirteen texts I selected and noting all the instances where any form of terms *dobro* and *blaho* is used. Then I performed a frequency analysis for each term.
2. Then I studied all the contexts in which terms *dobro* and *blaho* appear, classifying the semantic fields of both terms and separating them into two categories: quotidian usage, where they are simple words (e.g., *dobro nam zdi* – [it] has done good for us), and scholarly, where they function as philosophical or theological concepts (e.g., *sotvory Blaho* [create the Good], or *Trudna Dobrota* [Difficult Goodness]). Further on I analyzed these two categories separately.

⁸ I rely on the theory of Vladimir Propp, who proposes that words are the materials out of which the whole system of meanings of the text is built. [Propp, 1998].

3. Since one of the characteristic features of Skovoroda's philosophy is its dichotomous approach, I also selected all the opposing pairs for both terms (*blaho/zlo*, *dobro/zlo*, *dobro/lykho*, *dobre/lukave*⁹, etc.). They were statistically calculated and analyzed in their multiple contexts as well.
4. There is one other term that is very important for Skovoroda as a name of positive phenomena: *shchastia* (happiness). It is frequently combined with the concepts *dobro* and *blaho*; therefore, I also calculated and contextualized such combinations (*blaho/shchastia* and *dobro/shchastia*).
5. Based on the results of all aforementioned calculations, I made a chart of the principles by which Skovoroda used the lexemes *dobro* and *blaho*. The conclusions define the precise meanings the philosopher could give to these words and their dependence on different contexts.

SOME HISTORICAL BACKGROUND

Skovoroda's vocabulary was shaped under the influence of his linguistic environment. Consequently, even though he could imbue some words with new or additional meanings, his language remained the language of the Early-Modern Hetmanate and Sloboda Ukraine. For the sake of his audience, he had to adhere—to some extent—to their norms of word usage. It is conceivable that the philosopher wanted his texts to be read and understood by the average reader. But he also wished his audience to engage in his play on words, to solve his linguistic riddles, and by doing so develop their intellect and ethical stance. Thus, before going into an analysis of *dobro* and *blaho* in Skovoroda's usage, we have to consider these terms in the more general context of Early-Modern Ukrainian common language. It must be noted at the outset that the word *blaho* was not used in Old Ukrainian, which relied on *dobro* to communicate all the possible meanings of "the good." In Old Church Slavonic, on the other hand, both terms were employed.

The study of theological texts published in the Kyiv Metropolitanate from the end of 16th till the first half of 17th century¹⁰ demonstrates the following basic principles of how terms *dobro* and *blaho* were applied at the time:

1. The word *blaho* was not used in Old Ukrainian texts. It was always replaced with the word *dobro*. At the same time, texts written in Old Church Slavonic used both *blaho* and *dobro*.
2. The choice of lexeme in both cases depended not only on the linguistic situation, but also on whether the text was written in the low, medium or high style.
3. In Old Church Slavonic texts:
 - (a) the noun *blaho* and other words beginning with a "blah-" stem dominate over the term *dobro* and its derivatives
 - (b) the noun *blaho* and the adjective *blahe* are reserved for the high style; they are usually used in the context of sacred matters

⁹ *Zlo* and *Lykho* are semantically close terms that designate evil, trouble, misfortune, etc.

¹⁰ This is merely an outline. For further details see: [Dovga, 2016a; Dovga, 2016b; Dovga & Olishchuk, 2016].

- (c) the noun *dobro* and the adjective *dobre* are employed in profane matters, in reference to quotidian objects and phenomena (in most cases they serve as synonyms for *zruchne* [comfortable], *korysne* [useful], *krasyve* [nice], *pryvablyve* [beautiful, beguiling], *iakisne* [high-quality], etc.)
 - (d) both *blaho* and *dobro* can be used as synonyms when they define certain virtues; but even in such cases *dobro* is never used within a strictly sacral context, it can only mark phenomena that are between the sacred and the profane
4. In Old Ukrainian texts:
 - (a) the word *blaho* is absent
 - (b) in translations from Greek and Old Church Slavonic *blaho* is still replaced with *dobro* even though the latter lexeme sometimes erases the boundary between sacred and profane spheres, which is present in the original texts. For instance, the Greek terms τὸ ἀγαθὸν/τὸ κάλλον which in Old Church Slavonic are respectively translated as *blaho/dobro*, in Old Ukrainian are rendered as *dobro/dobro*.
 - (c) in quotidian situations the term *dobro* can be altered by *zatsnost'* (nobility), *tsydnost'* (excellence), *uroda* (beauty), *potikha* (fun), *roskosh* (luxury) or other synonyms
 5. We can be quite sure that when the intellectuals of the Kyiv Metropolitanate wrote (or translated) a text in Old Church Slavonic they always reserved the special high-register field for the term *blaho*.
 6. The noun *dobro* functions as an equivalent of the term *blaho* in Old Ukrainian texts, but its semantic field remains blurred till the middle of 17th century. Consequently, in this period it cannot be considered a clearly defined philosophical or theological term or concept.
 7. In the first half of 17th century, the boundary between styles (or registers) of language, namely between high theological discourse and low daily one, was demarcated by several factors. One of them was the choice of language itself¹¹: the “sacral” Old Church Slavonic vs “common” Old Ukrainian. The other was the choice of certain words within each of these languages and the separation of terms close in meaning, depending on their sphere of usage.

Things changed in the second half of 17th century, as we can see from the analysis of texts published by the press of the Kyiv Caves Monastery (Pecherska Lavra). In that period the situation looked like this:

1. In Old Church Slavonic texts the segregation between semantic fields of the terms *dobro* and *blaho* becomes clear and strict. *Blaho* is only for the sacral sphere, *dobro*

¹¹ In the Early-Modern Kyiv Metropolitanate sacral texts and theological literature were translated, written and published in both Old Church Slavonic and Old Ukrainian, though the former was dominant. Among the works published in Old Ukrainian the most significant are: *Peresopnytsia Gospels* [PG, 2011]; the translations of John Chrysostom included in *Likarstvo na ospalyi umysl cholovychyi...* [The Remedy, 1607], and the *Didactic gospel* by Cyril Tranquill Stavrovec'kyj [Stavrovec'kyj, 1619].

for the vernacular sphere, and cases of vagueness and in-between contexts are almost completely gone.¹²

2. The term *blaho* enters into the sermons written in Old Ukrainian.¹³ It is used to describe phenomena of the sacral world or some of the sacral elements as they are incarnated in the realm of the profane.
3. The word *dobro* does not gain a precise, strictly determined sphere of usage. But, as statistical analysis shows, in sacral contexts the term *blaho* dominates now.
4. Old Ukrainian vocabulary gradually develops a semantic differentiation between theological discourse and daily spoken language. It acquires certain new words that come from the high register, namely theological and philosophical scholarly style, and at the same time remakes some of its usual words into terms with more or less clear definitions and contextual fields.
5. The term *blaho* is adopted into Old Ukrainian writings by the intellectuals of Kyiv in the 17th century and later in the 18th. It functions as the term that draws a conceptual line between the vocabularies of two registers. It separates the “high” style of the sacral language from the “middle” style used to explain the sacral to “simple” people.

Finally, texts written in the first half and the middle of the 18th century demonstrate that at that time the situation became more or less stable. In these texts both lexemes seem to gain their semantic fields in both Old Ukrainian and Old Church Slavonic languages. The term *blaho* (and adjective *blahe*) function as the characteristic of:

- (a) God and His Gifts;
- (b) treasures of the Upper World;
- (c) ultimate satisfaction of the moral needs of humans;
- (d) ultimate goals and absolute value of human life;
- (e) absolute perfection, highest moral values, balance and harmony of the soul;
- (f) occasionally to designate acts of charity;

The term *dobro* (and adjective *dobre*) are used to describe:

- (a) moral virtues and other positive traits of a person’s character;
- (b) acts of charity and a person’s will to perform them;
- (c) physical beauty and attraction;
- (d) wealth and material goods (in such cases usually in plural – *dobra*);
- (e) anything pleasant, comfortable, helpful in a usual profane life;
- (f) work well done or a person’s ability to perform it (as a synonym to *staranno* [carefully], *uvazhno* [attentively], *sumlinno* [conscientiously]);
- (g) positive features of natural objects (such as good grain, good horse, etc.);

¹² This tendency is already evident in the translation of the *Commentary on the Apocalypse* by Andreas of Caesarea, published in 1625 [Andreas of Caesarea, 1625], and becomes constant since *Myr z Bohom choloviku* by Inokentii Gizel’ (1669) [Giesel, 1669].

¹³ The first author to introduce this term to Old Ukrainian vocabulary was Antonii Radyvylovs’kyi (See: [Radyvylovs’kyi, 1676] and [Radyvylovs’kyi, 1688]). It appears that he perceived this term to be foreign in the Ukrainian language; thus, in some instances he specially describes and explains it to his flock. See my analysis in [Dovga, 2016b].

In instances where the moral virtues of human beings are discussed, the semantic fields of *dobro* and *blaho* may still intersect in Old Church Slavonic texts, while in Old Ukrainian almost every such case is covered with the term *dobro*.

Worthy of note is the manner in which these terms were used in the plural. In modern Ukrainian the word *blaho* has a standard plural form: *bláha*. But *dobró* has lost its plural and is used only in the singular. In Early-Modern Old Church Slavonic and Old Ukrainian, we see the opposite. The word *blaho* is hardly ever used in the plural, but the plurals of *dobro* – *dóbr* and *dóbra* – are rather common. This might result from the fact that the sacral world in early modernity was perceived as a unified, monolithic entity, while the profane sphere represented a multiplicity of detached elements.

BLAHO AND DOBRO: THE PROBLEM OF INTERPRETATION AND TRANSLATION

As already mentioned, the difference between the semantic fields of *dobro* and *blaho* becomes especially relevant when translating Ukrainian philosophical texts into languages that do not have the means to express their difference. In the case of Skovoroda’s works it becomes even more complicated because, in addition to the traditional semantic distinction of these two words, a translator also needs to consider the author’s specific word usage. Skovoroda sacrifices the general rules of Old Ukrainian language to convey the philosophical sense with which he imbues words. At some instances he picks a certain word according to the subtle nuances of its meaning in a specific context, to the semantic peculiarities of its specific form, or even its sound or graphical appearance. Such details lead him to ignore usual grammar rules and even erase the boundary among different languages (e.g., Old Ukrainian, Old Church Slavonic, and standard Russian). He transforms words into the strings of a musical instrument, depending on which he touches and meaning he selects, the music changes its tone, key and character. As George Y. Shevelov noted, for Skovoroda: “*verbal experimentation conveys the ultimate truth, and the web of words becomes an adequate means to express the wealth and intricacy of God’s manifestations in the visible word.*” [Shevelov, 1994, p. 113].

Skovoroda “plays” the strings of *dobro* and *blaho* with subtlety and care. Hence before presenting my analysis of his works in a wider perspective, I would like to provide a case study on his word-usage and attempts at its interpretation in English. As an example, I chose the translation by an excellent specialist whose scholarship is very sophisticated. This makes my example of misunderstanding between author and translator highly representative.

Let us consider George Kline’s translation of *Razhovor piaty putnykov o istynnom shchastyi v zhyzni*, titled *A conversation among five travelers concerning life’s true happiness* [Skovoroda, Kline 1965].

In this colloquy the term *blaho* is used twice as a noun; it is not used adjectivally or adverbially (e.g., *blaho*, *shcho* or *blahyi*); but there are 25 other terms that begin with the *blah-* stem, such as *blahovonnyi* (fragrant), *blahovistvuiut* ([they] glorify, praise), *blahodaryty* (to praise, to thank), *blahodarnost’* (gratitude), *blahodat’* (grace), *blahopoluchiie* (prosperity,

well-being), *blahoprystoinist'* (decency), *blahorodnyi* (noble, decent, faithful), *blahosloven* (blessed), *blahoslovliu* ([I] bless, praise), *blahoukhannyi* (scented).¹⁴

The word *dobro* appears in this text three times as a noun and twelve times as an adjective (*dobryi*), but the stem *dobro-* appears in only six cases, among them: *dobroditel'* (virtue, goodness), *dobroditel'nyi* (virtuous, righteous), and *dobroserdechnyi* (kind, good-hearted).

Now let us consider Kline's translation of the fragments where the nouns *blaho* and *dobro* appear. In Skovoroda's text there are three such moments, but Kline translates only two of them:

Original text by Skovoroda	English translation by Kline
Яков: ... Вить тое, что лучше всего, то и выше всего, а что выше всего, то всему Голова и Конец. Сіе главнѣйшее <i>добро</i> ¹⁵ названо у древних философов Окончаніем всѣх <i>добр</i> и верховнѣйшим <i>добром</i> . Кто ж тебѣ может развязать, что такое есть Край и Пристанище всѣх наших желаній? [A Conversation]	For what is best of all is highest of all, and what is highest of all is the head and crown of all. This chief good was called by the ancient philosophers the “ultimate good” and the “ <i>summum bonum</i> ”. But who can unravel for you the homeland and haven of all our desires? [Skovoroda, Kline 1965]
Григорій: Потому что не разумѣм, в чем оно состоит. Голова дѣлу то, чтоб узнать: Отсюда родится желаніе, от желанія иск, потом полученіе. Вот и <i>благополучіе</i> , сирѣч полученіе, что для тебе <i>благо</i> . [A Conversation]	Because we do not understand in what it consists. The chief thing is to discover the source of desire. Desire seeks something and then receives it. This is <i>well-being</i> , that is, the getting of what is <i>good</i> for you. [Skovoroda, Kline 1965].
Лонгин: Длячего ж не зваться Ему Миром и Мира имущю Крѣпостью, если Он показывает, гдѣ Мир, и побуждает к нему, находясь сам всему <i>благу</i> Началом и Источником? [A Conversation]	Kline omits this section.

Scholars usually note the dichotomous nature of Skovoroda's writings, and *Razhovor piaty putnykov o istynnom shchastyi v zhyzni* is not an exception. The fragments given in this table include two main lines of thought pursued by the interlocutors. One of them is framed within the sphere of earthly life, it is profane, simple and mortal, while the other one leads to the sacral sphere, to the world of sacred and eternal truth.

The first fragment comes from the beginning of the dialogue. It initiates a dispute on earthly values. The five travelers are pondering the problem of happiness: what is it, and where can it be found. Their first solution seems to be the most obvious one: happiness can be found through possession of something good and desirable; the happy person has a lot of *dobro*. But Iakov appeals to the “wisdom of the ancient philosophers” (Aristotle, perhaps) and draws attention to another concept. He supposes the existence of the preeminent or highest good. His interlocutors support this idea. Yet Iakov does not explain what is so special about this good that brings true happiness to the individual. Either he does not know it, or he is not willing to reveal his knowledge yet. In this part of the colloquy the disputants limit their

¹⁴ Most of these words have synonyms that are not derived from *blaho*. Some examples from the *Lexicon* by Pamvo Berynda: *blahovisitiiie: dobraia povist'*; *blahodareniiie: diakovaniie, dobroie podiakovaniie; blahodarnyi: podiachlyvyi, vdiachnyi; blahodaru: diakuii; blahodat': laska; blahopoluchiiie: shchastie; blahoslovliaii: dobre movliu, khvaliu, vyslavliaii; blahoukhaniie: vdiachnyi zapakh* [Berynda, 1627, colum. 6-11].

¹⁵ In this table, all *italics* are mine – L.D.

search of happiness to the boundaries of the profane sphere; they only discuss earthly lures, such as high offices, riches, estates, intellect, beauty, health, fame, strong family, loyal friends, etc. But none of these can be possessed in absolute fashion. There is always going to be someone richer, wiser, healthier than you. It is difficult to imagine someone in complete possession of all of these. Moreover, experience shows that wealth, fame, beauty and the like frequently lead people to moral degradation, propelling them to evil deeds that can cause misfortune in private and social life.

Once the discussion about these issues is exhausted, Hryhorii initiates a new line of thought. He proposes to look for a real, True Happiness, not the fictitious one they have been seeking thus far. What they need is to abandon the land of profane, animal passions and turn to the path of moral development, which leads toward the Divine Wisdom and Light. This is the moment in the text where the "preeminent place" of *dobro* cedes to *blaho*. Skovoroda does not use any modifiers with the term *blaho*. He has no need to qualify it as "prime," "highest" or "ultimate," because it is already an absolute concept. Worthy of note is the manner in which Skovoroda changes his references here. When he has Iakov speak about *dobro*, he labels it as the "highest good" and cites the "ancient philosophers." But once the conversation turns to *blaho*, he introduces symbols taken from the Bible. Thus, the author distinguishes even more vividly the profane field of *dobro* from the sacral field of *blaho*.

For this reason, in this first piece of the text Skovoroda allows Iakov to use neither the term *blaho*, nor any Greek or Latin words. This part of dialog is set among "simpletons," the common folk, so the language has to have a suitable register. Kline's English translation of this fragment does not recognize this semantic difference. Kline could not find a proper English equivalent that would express the difference between *okonchaniie vsikh dobr* ["the highest level of all goods"] and *verkhovniishie dobro* ["the highest good"]. Therefore, he translated the first as "ultimate good" (which could have worked had he not made Skovoroda's plural concept of disunited "goods" into a singular "good"), while replacing the second with a Latin term. This usage of Latin contradicts the conceptual meaning of the whole text. At first, it might appear that the author himself had used this Latin term. The use of Latin automatically "upgrades" the language from common, daily speech to a "higher" register that creates an association with the sacral sphere. This association then confuses the readers, because at the beginning of the colloquy Iakov does not as yet address such matters. His mention of the "highest good" as *verkhovne dobro* (not *blaho*) is a powerful hint. It foreshadows the existence of a sacral sphere, but neither Skovoroda's characters nor the readers are invited to visit the sacred world yet. Quite the opposite, these hints merely initiate a long process of searching. The readers are going to dwell on detailed explanations for a good part of the text before they could reach the full understanding of the high sacral concepts. However, the English translation spoils the process by revealing the goal of the discussion at the very beginning of the text, prematurely simplifying the journey toward understanding.

The second fragment in the table argues that none of the earthly lures can make a person happy because they are not stable; a human being could never rely on any of them. The only thing that is really stable and reliable is a life in union with God. To live with God in your heart is the only way to gain true happiness. Happiness is *blahopoluchchiia*, which means acquiring the things that impart real *blaho* on a human being. This is the first place in this colloquy where Skovoroda replaces the term *dobro* with the term *blaho* to show the transition of the "good" under discussion from the profane to the sacral sphere. Here the readers'

journey takes them to the frontier, the place where the profane meets the sacral, the mortal meets the eternal, the human meets the Divine, the *dobro* meets the *blaho*. But the English translation does not make it clear, since “well-being” and “good for you” which are meant to express *blahopoluchchiia* and *blaho* cannot show this transition in any way. They are not distinct from the “ultimate good” which is used for *dobro*. The English equivalents used here are so quotidian that they draw this segment of the text back to the usual, profane world. Thus, the translation loses the deep didactic and philosophical sense intended by the author.

The last of the aforementioned fragments is fully dedicated to *blaho*, i.e., the true value, to which “(the Creator) himself is the Reason and the Source” (“[Творець є] сам всьому благу Началом и Источником”). It also emphasizes on the wholeness of *blaho*; this is why it is expressed in the singular “*vsionu blahu*,” not in the plural. “*Vsim blaham*” (plural) would not be possible for Skovoroda. Special attention is given to the omnipresence of *blaho*: it is a constant part of the whole of Nature. But in the English translation this part is just absent.

There is one more detail, which is prominent in the original text but lost in translation. The two discourses formed by the contexts of two terms – *dobro* and *blaho* – are connected by some elegant transitions, and so are the two worlds they represent – profane and sacral.

One of these transitions is the notion of happiness, *shchastia*. The ways Skovoroda uses this term and its possible meanings in his works may be the topic of an entire new chapter. Noteworthy here is the role of *shchastia* as a destination about which the debates in *A Conversation* turn. The concept of absolute happiness, which is the goal of life of any normal creature on Earth, serves to visualize the boundary between *blaho* and *dobro*. Therefore at the very end of the discussion the travelers agree that *blaho* is almost equal to *shchastia*, whereas *dobro* stands very far from both of them. It is not even on the way to either.

The second transition between the two spheres is constructed by composite words, e.g., “Вот и благополучіе, сирѣчь полученіе, что для тебе благо.” These words of Hryhorii could be roughly translated as follows: “Here you find well-being, which means the being that is well for you.” Both “well-being” in the main clause – *blahopoluchiie* – and “well” in the subordinate clause – *blaho* – are formed with the stem *blah-*. Therefore, this “well-being” cannot be simply replaced with Ukrainian *shchastie* (happiness), which is formally its synonym, as Pamvo Berynda’s *Lexicon* states. *Blahopoluchiie* is not just happiness caused by the good conditions of life. *Blahopoluchiie* is the state of receiving *blaho*, which in Skovoroda’s *Dialog* means entering into a unitive exchange with the Creator. I suppose, this is the reason why we find so many words with the *blah-* stem in this text. Usually this peculiarity of Skovoroda’s vocabulary is explained by the impact of Old Church Slavonic and Russian on his language. But, this is reductive reasoning. They are written with a definite purpose, i.e., to show the presence of the Divine in a human being’s daily life. Fragrant things are called *blahovonni*, the fresh air is referred to as “*svitlyi i blahovonnyi vozdukh*” that brings joy to people, whereas the scented smoke (*blahoukhannyi*) rises to the Creator. All those who smell like true *blaho*, their smell elevates the human spirit and delivers it to the God. A similar situation pertains to such terms as *blahodarite*, *blahodarnost’*, *blahodareniiie*. They all express gratitude in some way, but in Skovoroda’s text they can not be taken as synonyms of Ukrainian *diakovaniie*, *podiachlyvyi/vdiachnyi* or *diakuiu*, even though these words are also directly translated as “thanks”, “grateful” and “thank you.” When the philosopher uses these composites with *blaho* he refers to the transfer of *blaho* from the sacred sphere to earthly life, when human express thanks to the Lord for his Grace. This is not about the simple “thanks” that we say to each other every day. When Skovoroda wants to speak about positive things in

our daily life or the positive features of a man, he uses the term *dobro* or its derivatives. For example “*k dobromu dilu*” is applied to a good business, “*dobryi konets*” to the good end, while “*dobryi liude*” means “good people.” A number of similar composite words—like *dobroditel’nyi* or *dobroserdechnyi* (could be translated as virtuous, righteous, kind)—refer to some specific ways in which people can be “good.” Skovoroda uses the *dobro*- stem words much more rarely than the *blaho* compounds, since the human world makes only a tiny part of the Great World made by the Creator.

BLAHO AND DOBRO IN THE CONTEXT OF SKOVORODA’S COLLOQUIES

As my analysis of the *Razhovor piaty putnykov o istynnom shchastyi v zhyzni* shows, this text makes a strict distinction between two types of “the good.” The term *blaho* is reserved for the sacral sphere and the reflections that God’s Grace makes on human life, while the term *dobro* is mostly used to describe the profane realities of the earthly world. But does such a distinction work in all of Skovoroda’s writings? Could one claim that he confers these two Ukrainian words with certain permanent semantic fields and thus entitles them to represent specific philosophical concepts? To answer these questions I propose to analyze a wider selection of his texts and see if this rule is true for all of them.

First, let us turn to statistical data. In the selection of 13 works that I have studied,¹⁶ the term *blaho* appears altogether 98 times: as a noun it appears 15 times; as an adverb 15 times; as an adjective (*blahyi* in three gender forms and two numbers) 68 times. There are 140 cases of *dobro*: as a noun it appears 24 times (once in a diminutive form *dobretsa*); the noun *dobrota* (a derivative, meaning “kindness”) appears 12 times; as an adverb *dobro/dobre* appears 10 times; as an adjective *dobryi* (in three gender forms and two numbers) 94 times.

As we can see, in Skovoroda’s works, the general usage of the term *dobro* in its multiple forms predominates significantly over the term *blaho*. Yet, when one reads these texts, *dobro* is far less visible than the numerous compounds utilizing *blaho*. The analyzed texts give us 324 examples of the latter, while there are only 21 terms combined with *dobro*. I will propose an explanation of the possible reasons for this later in this chapter.

Hryhorii Skovoroda used the term *blaho* as a philosophical concept with a strictly determined semantic field. Analysis of the listed texts demonstrates it very clearly. He only uses this term in the context of something sacred, be it the sacral world itself or the narrow “borderland” where the two worlds intersect and where the ultimate meaning of human life can be found. If an individual or a society attempts to imitate the Divine, thus bringing some sacred elements into the profane world, such efforts are also defined as *blaho*. Here I would like to provide a more detailed illustration of how the semantic fields of *blaho* work in Skovoroda’s texts. With this purpose in mind, I list the examples of different applications of this term in accordance with their contexts:

1. *Blaho* works directly as an alternative name for the Creator or as His symbol: *Сеї єсть один родник неисчерпаемый всему благу и блаженству нашему, он сам*

¹⁶ See the list of these texts in the Primary Sources section of this chapter.

- есть оное блаженство, безвиновное НАЧАЛО ... Сія высочайшая вина всеобщим именем именуется БОГ¹⁷ [The Circle]; Кто благ? или кто мил, кромѣ Бога? [Conversation The Two]; ...Она есть Лѣствица, Все возводящая к Богу. Он Един благ и Един высок. [The Serpent's Flood]; ...не благѣй ли Дух? а Дух благѣй не тожели, что БОГ? ... кромѣ Бога, ничтоже Благо [Lot's Wife].
2. *Blaho* is associated with the Creator through the mediating notion of Nature¹⁸: Природа Благая есть Всему Начало и без нея Ничтоже бысть, еже бысть БЛАГО. [Herodius].
 3. *Blaho* characterizes the Upper World and its creatures: Великая и благая Дума Есть-то Главный Ангел, вѣсть благая, Совѣтъ прав... [Conversation 2].
 4. *Blaho* expresses the idea of the direct impact of God: Сіе Иго велми Благо и Легко есть... [Conversation The Two]; Иногда, де, во убогом Домикѣ, исполненном Страха Божія, Друг Роду Человѣческому Благо рождается ЧЕЛОВѢК, ... яко не Красота Мыра сего, ни Тварь кая-либо, но едина Благодать Божія Благому Рожденію Виновна бывает. [Herodius].
 5. *Blaho* expresses the presence of God's Will in certain earthly phenomena, usually a person's deeds or thoughts: Однак благая во мнѣ дума [Conversation 2]; ...как всякое благое Дѣло в зачатіи и в коренѣ горкое... [Conversation 2]; Двѣ суть Главныя Родительскія Должности сіи: "БЛАГО родить и БЛАГО научить [Herodius]; Воспитаніе же истекает от Природы, вливающія в Сердце Стѣмя Благія Воли... (Herodius); ...здравая и мирная душа благія пристрастности любит..." [Plutarch].
 6. *Blaho* defines the highest value as the ultimate goal of a human being's life: Вся испытайте, благая же пріемлите [Conversation The Two]; Сыне мой! ... учися единыя Благодарности. ... Ты рожден еси Благо, и сія Наука есть Дщерь Природы твоя... [Herodius]; БЛАГА МУДРОСТЬ ... паче же видящим Солнце [Icon of Alcibiades]

In the above quotations the term *blaho* can probably be replaced with the Greek equivalent τὸ ἀγαθόν and translated in English as "Highest Good" or "Ultimate Good."

The application of *dobro* and its derivatives in these texts has many more diverse semantic fields. First of all it works as an adaptation of *blaho* for realities of the profane world, which makes this high concept easily understandable for simple people. An example of such usage can be found in Herodius: "Ничтоже бо есть Бог, точію СЕРДЦЕ Вселенныя, наше же Сердце нам же есть ГОСПОДЬ и ДУХ. Сіе Домашнее они свое БЛАГО со Временем узнав и плѣнився Прекрасною ЕГО Добротою, не станут безобразно и бѣсновато гонитися за Мырскими Суетами..."[Herodius]. *Dobro* may also stand for the positive characteristic of earthly phenomena. It defines profane things, deeds and ideas that are appropriate and truthful. In such instances, it might be seen as a reflection or a shadow cast by *blaho* into the world of human beings. Yet *dobro* can also gain negative

¹⁷ Here and subsequently, I quote Skovoroda only in the original, for fear that any translation of his sophisticated play on words can be unclear or, at best, misleading. The orthography and formatting of the original is preserved.

¹⁸ Almost all of the scholars who study the philosophy of Skovoroda point out that he tends to treat Nature and the Creator as equal notions. E.g.: [Bilaniuk, 1994; Chyzhev's'kyi, 2003; Kline, 1994; Kline, 1997; Popovych, 2008; Ushkalov, 2001]. Yet the linguistic analysis of this specific feature remains undeveloped.

connotations and stay in opposition to *blaho*. Skovoroda frequently turns to the word *dobro* when speaking about the elements (e.g., wealth, health, physical beauty, high offices, manors and lands, intellect, fame, power, etc.) that people erroneously confuse with aspects of true happiness. In fact, this is the main difference between *blaho* and *dobro*. The former is always real and is eternal. The persons who do *blaho*, want *blaho*, struggle for *blaho*, aim at *blaho* in their life are always right. Such persons cannot be mistaken, their path is truthful, therefore they cannot possibly be let down or cheated. The reward is waiting at the end of their difficult journey. *Dobro*, on the other hand, may be fake, deceptive and temporary. *Dobro* is plural and it seems to provide many alternative ways in life. But the person who falls into temptation and chooses *dobro* over *blaho* is in fact cheating the self. Trapped by earthly passions, such a person is bound to loose more and more life energy while accumulating more and more needless *dobra* (pl.), and finally gets frustrated. This road leads a person toward complete unhappiness, away from God and his *blaho*.

Let us have a closer look at the different contexts where Skovoroda employs the term *dobro*. Again, I list the examples according to their semantic fields and possible implemented connotations:

1. An element of the sacral world, God's creation or the secret knowledge of God ("fundamental *dobro*"): *На сіе доброе свое дѣло взирал ВЫШНІЙ добрым своим Оком*. [Icon of Alcibiades]; *Сіи суть добрыя дѣвы...* [Conversation 2]; *...от сих же Источников раждается двойный вкус в Библии: Добрый и Лукавый, спасительный и погибельный...* [Conversation 2]; *ДОМ БОЖІЙ. ... что добро, и толь красно, яко ДОМ ЕГО?* [Conversation 2]; *Добрый и злый Ангел приставляются в рожденіи каждому чловѣку...* [Plutarch]; *... называя ЗДБ остающихся Людми, вѣдущими ДОБРО и ЗЛО, каков, видно, был Адам, изгнанный из Рая*. [The Serpent's Flood].
2. Something positive, praiseworthy, desirable, charitable, truthful: *Τό κάλλος χαλεπὸν ἐστί. Трудна Доброта* [Conversation The Two]; *Вот тебѣ от мене награда! За твое доброе Слово!* [Conversation The Two]; *...имѣть Дома, внутрь себе, все свое некрадомое Добро* [Herodius]; *Наше Добро во Огнь не горит, в Водѣ не тонет, Тя не тлит ...* [Herodius]; *Добрыи Плоды, приносиміи Богу* [Herodius]; *Фортуна ... над истинным добром твоим не имѣет власти* [Plutarch]; *Тогда сердце дѣлается доброю нивою, падает и пріемлется ВѢЧНОСТИ Зерно* [Lot's Wife].
3. A positive feature of a person or a natural phenomenon, also a sign of harmony between a person and human nature: *Поговори еще мнѣ о добрых Птицах* [Conversation The Two]; *Рожденнаго на Добро не трудно научить на Добро...* [Herodius]; *Как же не противно разуму бѣситься и мучиться тѣм, что не всѣ тѣ добрыи и вѣжливы, с коими нам жить довелось?* [Plutarch].
4. Praiseworthy moral deeds: *За добрую же славу лучше желает Павел умиръ* [Conversation 2]; *Если Совѣтъ добр, то и плоды добрые...* [Lot's Wife].
5. Its negative meaning can be discerned where the earthly world's vanity, false aims, delusions abide: *Оно Глупомудрым Сердцам видится Добром, по Естеству же своему есть лукавое*. [Dialog or Discourse]; *Конечно, сей Змій есть тот же, что нашенгал Евѣ, будто у Смертнаго Древа добрый Плод* [The Serpent's Flood]; *...есть нещасливая душа, щастіе свое на пѣску стихійном основавшая*

и утвердившая себя, что можно добро свое сыскать внѣ Бога ... По сему видно, что все свѣтское добро нѣсть добро; оно сокрушается... [The Circle].

Finally, there is one more important element which helps to define the semantic distinction between *dobro* and *blaho* in Skovoroda's works. This is the way he chooses antonyms for each of term. Since the dichotomous approach is one of his most usual philosophical instruments this detail cannot be omitted from my analysis.

In all analyzed texts there is only one antonym for *blaho* – *zlo* (evil). It appears in eleven out of eleven antitheses. A couple of examples will suffice: “Ангел благій и злый... благій и злый Дух” [Conversation 2]; “Уклонися от зла и сотвори Благо” [Conversation on The Two]. In contrast to *blaho*, the term *dobro* has a lot of antonyms. The first and most frequently used is the noun *zlo* and the adjective *zlyi*; it appears thirteen times in the texts (e.g., “Таков, аще себѣ Зол, Кому добр будет?” [Herodius]; “Добро и Зло, Нищету и Богатство Господь сотворил и слѣпил во ЕДИНО” [The Serpent's Flood]). The second most used word pair is the noun *lukavstvo* and the adjective *lukavyi*, which could be approximately translated as “wicked” or “cunning.” These can be seen in such cases, as “лукавое и доброе, лжа и Истина” [Conversation 2] or “видится Добром, по Естеству же своему есть лукавое” [Dialog or Discourse]. The total number of such cases is nine in all texts. But I also found such antitheses as *dobryi* – *smertnyi* (mortal): “будѣто у Смертнаго Древа добрый Плод” [The Serpent's Flood]; *dobroe* – *durnoie* (bad): “Будѣто чрез нея ... дурное случилось или нѣчто доброе не досталось” [Plutarch]); *dobryi* – *pustyi, khudyi* (vain, shallow); *dobroe* – *rastlinnoie* (corrupted, immoral) and a many others. The opposition between *dobro* and *zlo* is fundamental. This refers to that eternal struggle between good and evil, which generates the dichotomous nature of our world and always forces humans to make a choice. However, the opposition between *blaho* and *zlo* has another meaning. It could also be interpreted as the war of Good and Evil. In this case both words are capitalized, since this pertains to concepts of the high register. *Blaho* with its antagonist *Zlo* is used to speak about the God's wisdom and His Will in the struggle against demonic Evil. In fact all applications of *zlo*—with *blaho* or *dobro* being its antonym—convey the concept of evil as a matter of choice. The term *zlo* never refers to a mistake or a delusion, but always to the conscious decision a person makes within the struggle between Light and Darkness, between God and the Dark Forces. This decision is principal for the author and must be understood as such by his readers. In cases where Skovoroda posits *lukavstvo* as an antonym of *dobro* he is speaking about a mistake, a situation when a person was cheated by his/her human passions. The importance of making a decision is also present in this context: a person has to choose *dobro*. But it appears that this is not a principal matter with *lukavstvo*. All other antonyms of *dobro* bring us to matters of daily life, they are mostly descriptive and do not bear any philosophical or ideological weight.

CONCLUSION

Many more examples could be used to shed more light on the nuances of the semantic differences between *dobro* and *blaho*. But the analysis I have provided allows me to draw a few conclusions:

1. Hryhorii Skovoroda defines a clearly limited field of usage for the term *blaho*. He reserves it for topics concerning the Creator, the Sacral World, and the reflections of certain sacred phenomena in the human world in the form of true absolute values and ultimate goals. This term is not used to describe the moral virtues of a human being or any deeds motivated solely by the human will. These strict contextual limitations convince us that the term *blaho* functioned as a definite philosophical concept in Skovoroda’s system.
2. This conclusion is supported by the vast number of compound words that begin with the *blah-* stem in Skovoroda’s works. The presence of God in human life and the projection of His Will into the earthly world are “visualized” by some symbolic events or images. Such reflections or shadows of the Sacral can be seen through the *blah-* elements, which affect certain profane objects. This is how we get *blahopoluchiie* (literally “the receiving or gaining of *blaho*,” meaning well-being, prosperity), *blaho-darnist’/blahodareniie* (literally “the giving of *blaho*,” meaning gratitude), *blaho-rodstvo* (literally “the innate *blaho*,” meaning righteousness, faithfulness, also nobility, but in moral terms rather than nobility of birth), and so forth.¹⁹ These derivatives of *blaho* could be called the terms of the intersection. Their semantic fields lie within the boundary where the sacral and the profane worlds meet.
3. In Skovoroda’s texts, the lexeme *dobro* is applied only to the earthly world. Even in cases where it is used to describe or explain the term *blaho*, it does not serve to complete this high concept in any way. The *dobrota* (“goodness”) of *blaho* may occur when the text addresses simple human beings whose imagination is limited by the profane sphere, and therefore the sacred notion has to be explicated in a way accessible to them. *Dobro* is also used to define highly moral human deeds, as well as other positive and praiseworthy aspects of daily life. This is a likely explanation for a comparatively small number of *dobr-* stem words in the philosopher’s vocabulary. A logical conclusion here would be that *dobro*, as well as *blaho*, has a strictly determined semantic field, and it is out of the philosophical terminology used by Skovoroda. In other words, *dobro* is not a concept; it is just a descriptive word.
4. The word *dobro* is often used in the context of daily life as part of colloquial language. Here its senses are rather blurred and diverse, but again it is definitely not a special term.
5. According to Skovoroda’s vocabulary, one could place *blaho* in hierarchical dominance over *dobro*. At the same time *dobro* —together with its analogs *dobrota*, *dobrist’* and the like—are clear, accessible and desirable for every human being. Meanwhile *blaho* is connected with moral advancement and development, and so may become difficult to obtain. Therefore the *dobrist’* – goodness and need – of

¹⁹ This what Skovoroda says on this matter: *Развѣ же То не Тожеде есть: Благое чествовать и Благій Дар за Благо почитать? Благочестіе чествует тогда, когда Благодарность почитет за Благое. ... Благочестность есть Дщерь Благодарности. Сыне мой! ... учися единья Благодарности. ... Ты рожден еси Благо, и сія Наука есть Дщерь Природы твоя ... Благодарность же есть Твердь и Здравіе Сердца, приѣмлющаго Все во БЛАГО и укрѣпляющагося. ... Во Благодарности (рече) так сокрылося всякое Благо, как Огнь и Свѣтъ утаился во Кремешкѣ. [Do you think that there is no Tozhda: Honor to honor and Good Gift for the Benefit to read? Piety is honored when Gratitude honors the Good. ... Piety is the Daughter of Gratitude. My son! ... learn the same Thanks. ... Thou art born a blessing, and this Science is the Daughter of Nature is yours ... Gratitude is Tverd and Health of the Heart, thanks to All in BLESS and in Ukrainian. ... In Gratitude (speech) every Good has been concealed, as Fire and Light hid in Krymeshk] [Herodius]*

blaho is not necessarily obvious. Sometimes it has to be especially explained to the people who are captured by love for earthly attractions, pleasures, profits and other advantages.

6. Concerning the translation of Skovoroda's oeuvre, it is important to note the contexts of his word-usage can give us an idea of how to find the best equivalents. I suggest that the closest analogy of *dobro* would be the Greek terms κάλλος (τὸ κάλλον) or τὸ εὖ, and in English the Everyday Good. For *blaho* I would propose to use the Greek term τὸ ἀγαθόν and English the Highest Good or the Ultimate Good.
7. The demarcation line between *blaho* and *dobro* that we see in Hryhorii Skovoroda's works is also present in most of the philosophical texts of the 17th century written in Old Ukrainian. *Blaho* is always truthful and reliable, for it belongs to the Creator; it can be performed only by His Will and Grace, and serves as a kind of emanation of the Sacred into the profane sphere. *Dobro* may be true if it is an earthly analogy of *blaho*, but it may also be fake; it may appear to be positive and useful while really being wrong and evil. Such imaginary *dobro* or "individual *dobro*" that is aimed at personal, temporary needs might prove to be evil for the others (or for society) since it does not contain absolute *dobrist'* for everyone. In many cases it leads a person to *zlo*, which may be followed by death.

BIOGRAPHICAL SKETCH

Larysa Dovga

Affiliation: National University of “Kyiv-Mohyla Academy”, Kyiv, Ukraine

Education:

- 2008 – 2011: Doctoral Study (Degree Doctor Hab. of Philosophy), Ukrainian National Academy of Music (Kyiv)
- 1989 – 1991: Doctoral Study (Degree Doctor of Philosophy), Taras Shevchenko National University of Kyiv
- 1977 – 1983: Diploma of Higher Education, Theory and History of Art Department Kyiv State Art Institute, Kyiv, Ukraine

Business Address:

National University of Kyiv-Mohyla Academy,
2 Skovorody str., Kyiv 04070, Ukraine

Research and Professional Experience:

Work experience:

- 2016 – Present: Full Professor at the Cultural Studies Department, Faculty of Humanities of National University of “Kyiv-Mohyla Academy”
- 2011 – Present: Visiting Professor at the History Department, Faculty of Humanities of National University of “Kyiv-Mohyla Academy”;
- 2005 – 2016: Full Professor at the Department of History and Theory of Culture, Historical and Theoretical Faculty of Ukrainian National Academy of Music (Kyiv);
- 1993 – 2011: Senior Researcher at the Department of History of Ukrainian Philosophy, Institute of Philosophy named after H.S. Skovoroda of National Academy of Science of Ukraine, Kyiv;
- 1983 – 1989 Senior Researcher, Museum of Ukrainian Fine Art, Kyiv, Ukraine

Professional Activities:

- 2007 – 2012: Project Leader, editor: Inokentii Gizel. Selected works in 3 volumes (published in Kyiv, 2009 – 2012)
- 1999 – 2014: Executive Secretary, Peer Review Almanac: Ukrainian Humanities Review
- 1997 – 2016: Executive Secretary, Society of Central and Eastern European Researchers, Kyiv, Ukraine;

- 1995 – Present: co-head of weekly methodological seminar "Problems of medieval and early Modern history of Ukraine" for graduate students and young scientists, (NaUKMA), Kyiv, Ukraine;
- 1996 – 1998: Project Leader: "Poetic Gnosis and Culture: An Anthology of Ukrainian Sermons of the end of XVI century - the beginning of the XVIII century"
- 1996 – 2001: Program Coordinator: Model UN – Ukraine 1993 – 1996: Executive Secretary, National Association of Ukrainian Studies Scholars, Kyiv, Ukraine
- 1992 – 1998: Co-editor: scientific almanac "Medievalia Ukrainica: mentality and history of Ideas".

Honors:

- 2013: Doctor Hab. of Philosophy. Thesis The value system in the Ukrainian culture Of the second half of the XVII century (on the basis of theoretical heritage of Inokentii Gizel); thesis defended in the Taras Shevchenko National University of Kyiv;
- 2001: Senior Research Fellow in aesthetics; approved by the Academic Council of the Institute of Philosophy named after H.S. Skovoroda of National Academy of Science of Ukraine, Kyiv;
- 1991: Doctor of Philosophy. Thesis: "Aesthetic Basis of Baroque Culture". Thesis defended at the Taras Shevchenko National University of Kyiv.

Chapter 20

MORPHOLOGICAL VERSUS PHONOLOGICAL AWARENESS IN CZECH READERS: A CASE OF TRANSPARENT ORTHOGRAPHY

***Jiri Jost*, Helena Havlisova, Ludmila Zemkova
and Zuzana Bilkova***

University of South Bohemia, Ceske Budejovice, Czech Republic

ABSTRACT

The aim was to investigate the relationship between morphological awareness and reading in a language environment which is phonologically transparent and morphologically challenging, i.e., the Czech language environment. The sample consisted of 171 typically achieving elementary school students (3rd to 6th graders). Morphological awareness and phonological awareness both had comparable influence on reading across all age levels, from the lowest (3rd graders) to the highest (6th graders). Morphological awareness affected reading speed and accuracy more than phonological awareness. Paradoxically, morphological awareness affected reading comprehension less than phonological awareness – authors interpreted this to be due to superficial reading style which manifested itself regardless of student age, gender or IQ. Implications for improvement of reading were discussed.

Keywords: morphological awareness, phonological awareness, transparent orthography, reading comprehension, reading speed, reading accuracy

INTRODUCTION

The focus of morphological awareness is on morphemes, i.e., the smallest meaningful word parts. Morphological awareness is characterised as the ability to identify the morphemic structure of words, identify morphemes and manipulate them, and classify words according to

* Corresponding Author Email: jost@pf.jcu.cz.

their collective meaning (i.e., teach, teacher, teaching) or according to their morphemic structures (i.e., teacher, farmer, driver) and thus create word families. In the last 10 – 15 years there has been a surge of interest in morphological awareness, with researchers showing interest in the relationship between morphological awareness and reading acquisition. The reason is the inherent nature of morphemes as elemental bearers of the word meaning – morphological awareness is studied in relation to understanding (Carlisle, 2000). The contribution of morphological awareness to decoding was confirmed by Carlisle and Stone (2005). For example, two-syllable words equal in frequency were more easily decoded when composed of morphemes in contrast to words composed of one morpheme only (i.e., *shady* vs. *lady*; *hilly* vs. *silly*). Carlisle and Fleming (2003) demonstrated that 1st graders were already sensitive to the morphemic structure of words, and decoded words using morphemes. This finding was most recently confirmed by, i.e., Wolter, Wood, and D'zatko (2009) and Berninger, Abbott, Nagy, and Carlisle (2010). Readers were stimulated to use morphological decoding when the words were phonologically transparent. That is, where the root word was intact in the derived word, students read words such as *growth* and *warmth* more fluently and accurately than *health* and *fifth*. Clin, Wade-Woolley, and Heggie (2009) used the term *morphophonology* to refer to the interaction between these skills or their facilitatory effect on reading. Deacon and Kirby (2004) concluded that morphological awareness uniquely influenced reading pseudowords. The contribution of morphological awareness to reading pseudowords was surprising because pseudowords carry no meaning. Their findings challenged the assumption that reading pseudowords was mainly dependent on phonological awareness, and showed that children perceived pseudowords as morphemic units. The contribution of morphological awareness to reading pseudowords was also confirmed by other authors, i.e., McCutchen, Green, and Abbot (2008). McCutchen et al. (2008) suggested that morphological awareness in reading words or pseudowords was facilitated by recognition of their orthophonological structure even without the presence of the semantic aspect. Semantic decomposition only occurred when orthophonological mapping was complete.

Morphological awareness in its implicit form is observable in children who are just beginning their schooling and probably occurs even in pre-schoolers (Carlisle & Fleming, 2003; Wolter, Wood, & D'zatko, 2009; Berninger, Abbott, Nagy, & Carlisle, 2010). Sensitivity to morphemic word structure seems to be an advantage that facilitates reading development. Conversely, a lack of sensitivity is a block in the reading development. The influence of morphological awareness on reading increases with school age (i.e., Arredondo, Ip, Ju Hsu, Tardif, & Kovelman, 2015; Deacon & Kirby, 2004; Mahony, Singson, & Mann, 2000). In their longitudinal study, Berninger, Abbott, Nagy, and Carlisle (2010) concluded that effective reading acquisition requires an interplay of all three components of linguistic awareness: phonological awareness, morphological awareness and orthographic knowledge. Using growth curve analyses, Berninger et al. (2010) showed that phonological awareness and orthographic knowledge increased the most during early days of schooling, while the acceleration of morphological awareness was spread out over the first three to four years of schooling, and some components of morphological awareness (derivative morphology) continued to increase significantly even after this time. Although morphological awareness began developing soon after a child began schooling, its overall development trajectory had a much longer range than other components of linguistic awareness. Studies on the unique and significant contribution of morphological awareness on reading ability sparked efforts to train morphological awareness and thereby improve reading and spelling (for review see Carlisle,

2010). In their meta-analysis, Goodwin and Ahn (2010) summarised results of 17 independent studies which investigated the effect of morphological instruction on literacy outcomes in students with literacy difficulties. Overall, morphological instruction caused significant improvement in literacy achievement. Rather than exercises focused exclusively on morphological skills, morphological exercises were much more effective when part of comprehensive intervention, i.e., in addition to morphological training, a course may also have included exercises on phonology, vocabulary, style and syntax. Goodwin and Ahn (2010) showed that morphological training significantly improved phonological awareness. Both linguistic aspects were connected and difficult to separate. Improving one aspect also improved the other. Goodwin and Ahn (2010) argued convincingly that morphological training should be utilised in addressing reading and spelling difficulties, and their prevention.

Czech vs. English and Reading Acquisition

Just like English, Czech is also a morphophonemic language. The spelling system utilises sound units (phonemes) and semantic units (morphemes). Although English is characterised as a non-transparent language which places high phonological demands on the reader, Czech with its high consistency is “phonologically friendly” – the letter corresponds to the sound, which is written as it is pronounced. While English is said to be morphologically simple, Czech is the opposite. Thanks to phonological transparency, Czech 1st graders read coherent texts fluently and with comprehension in the first half of the 1st grade. A proven method is the analytic-synthetic method of teaching reading, which is applied to about 95% of all children (CSI, 2014). It is based on the fact that Czech spelling is essentially phonological. As the term suggests, it combines the analytical process (i.e., the decomposition of words into syllables and phonemes) and the synthetic process (i.e., joining letters into syllables and words). In early reading practice pupils at start with reading separate syllables and after this stage pass to reading of whole words. While practicing a new letter, the relevant word is deduced from speech. The word is further analysed into syllables and sounds, which are then assigned to letters. The synthetic stage includes joining letters into other syllables and words, and later also writing these words. Children are simultaneously taught reading and writing and familiarise themselves with all the written forms of sounds – the correlation of reading and writing is an essential feature of this method.

Owing to the nature of the Czech language and the relatively rapid development of reading skills in a typically developing child, reading tests are not just lists of words, but coherent texts that are administered in the first half of the 1st grade. Reading speed seems to be the best measure of reading level in an individual child. Typically developing Czech children make very few mistakes when reading continuous texts (about 1-2% in 4th, 5th and 6th graders; see Matejcek, 1998). The correlation between the number of incorrectly read words and reading speed is very low. This means that fast readers do not make more errors on average than slow readers (Matejcek, 1998). The average Czech child reaches socially acceptable level of reading in the second half of 2nd grade or in the first half of 3rd grade (Matejcek, 1998); it means that a child is able to read coherent texts fluently, quickly enough and without mistakes (the number of words read correctly per minute is about 60 to 65 on average, and the percentage of error around 1-2). A child can read children’s books for pleasure and also interact with the textbook.

Czech morphology is complicated. A rough outline is offered in the supplementary material.

The Aim of the Present Study

Research has already provided evidence that morphological awareness plays an important role in reading acquisition in English-speaking children. We decided to undertake this study because morphological awareness in relation to reading has not yet been investigated in the Czech Republic. We asked ourselves whether morphological awareness exercises any effect on reading in the Czech language environment. Owing to the nature of Czech, which is characterised by higher morphological complexity than English, it is expected that the impact of morphological awareness on reading in Czech will be greater than in English. Another reason for this hypothesis is high grapheme-phoneme consistency of Czech. The research shows (Carlisle 2000; Carlisle & Stone 2005) that pupils spontaneously use their phonological skills to identify morphemes. When conditions are favourable (i.e., phonological transparency), pupils naturally apply the morphological strategy when decoding words and they are trying to identify the word through its morphemes. Because the Czech language is transparent, this characteristic will, among Czech readers, naturally stimulate morphological strategy to a greater extent than in English.

METHOD

Participants

The participants were typically developing elementary school pupils ($N = 171$, 93 boys, 78 girls) ranging from 3rd to 6th grade (3rd graders $n = 59$, 4th graders $n = 37$, 5th graders $n = 48$, 6th graders $n = 27$). This age range was chosen in order to use an identical test. Czech children begin attending school at the age of 6 years. This means that 3rd grade included 9-year-olds and 6th grade included 12-year-olds. All participants were monolingual Czech speakers; Czech was the mother tongue of both the children and their parents. Neither neurodevelopmental disorders (intellectual disability, communication disorder, autism spectrum disorder, attention-deficit/hyperactivity disorder, motor disorder, specific learning disorder) nor trauma- and stressor-related disorders, disruptive, impulse-control, and conduct disorders, problems related to family upbringing, child abuse and neglect were documented in the participants. The participants were healthy, without serious pediatric finding. The participants came from seven elementary schools in four regions (South Bohemia, West Bohemia, Central Bohemia and Highlands/Vysocina, In Czech/). All participants were learning to read through the analytic-synthetic method. All children came from middle class families. The Czech Republic is highly homogeneous in terms of ethnic composition. The data were collected in the years 2014 to 2016.

Measurements

Reading

Reading was measured using a standardised test (Matejcek, Sturma, Vagnerova, & Zlab, 1992) and defined as a reading quotient (RQ). RQ is a standard score that is comparable to the IQ score and is based on the number of correctly read words per time unit. Speed and accuracy are merged into one complex parameter “number of correctly read words per time unit”, because Czech children read with high accuracy from the very beginning of reading development (Kucharska et al., 2015; Matejcek, 1998; Matejcek, Sturma, Vagnerova, & Zlab, 1992). The RQ in the Czech language environment (i.e., a phonetically highly consistent orthographic system) largely correlated to comprehension (Matejcek, 1998). For this reason, the comprehension test was not standardised in the Czech environment. Absence of the comprehension test was therefore not a substantial drawback, even though its application would have been enriching.

Each pupil read aloud a text containing 245 words. The investigator registered: a) the total time required for reading the entire text, and b) the number of words read incorrectly. When the pupil finished, the investigator verbally administered 22 questions with which he assessed reading comprehension. The pupil had no chance to see the text again. For example, the pupil read a part of the text saying: “A procession of aged animals came along to the sovereign of underground, the mole.” The investigator asked: “Who came along to the mole?” If the child answered: “A procession of aged animals”, the answer counted as 1 point. The answer: “A procession of animals” earned the child half a point. Reading comprehension was expressed by a number of points: a pupil could receive a maximum of 35 points, i.e., perfect and detailed understanding of the read text.

Morphological Awareness Task

This was constructed for the purpose of this study and has not yet been standardised in the Czech Republic. In terms of content validity, we based our test on information about Czech morphology found in the elementary school curriculum. Its structure has been described in section Supplementary Material. The test was administered individually without time restrictions. There was always a practice question for each question which tested a particular morphological phenomenon and this was followed by the test itself. The subject could receive a maximum of 65 points where 1 point was equal to 1 correct answer. Split-half reliability: $r = 0.897$ ($N = 171$, $p = 0.000$).

Phoneme Analysis and Synthesis

Matejcek’s diagnostic task (1993) was used. In the analytical part of the task, the investigator told the child a real word and asked the child to divide the word according to letters and to maintain their order, i.e., pes (= dog) $\rightarrow$ p – e – s. In the synthesis part of the task, the investigator divided the word into letters while maintaining their order, and the child was then supposed to pronounce the word. In both parts, there were 10 words with 1 or more syllables. Performance was evaluated as follows: if the child responded correctly in its first attempt (i.e., it divided the word or put the word together correctly), it received 2 points. If it failed in its first attempt, the investigator repeated the word. If the child succeeded in dividing the word or putting it together successfully in its second attempt, it received 1 point. If the

child failed in its third attempt, it received 0 points and the investigator moved on to the next word. It was possible for the child to acquire a maximum of 20 points in the analytical task and 20 points in the synthesis-based part.

Phoneme Deletion

This test consisted of two sets of monosyllabic pseudowords (Caravolas & Volin, 2005). Each set contained 10 pseudowords. The first set contained pseudowords with CCVC structure, while the second set contained pseudowords with CVCC structure. All pseudowords respected Czech phonotactic rules and were easily pronounceable. Each tested child heard a pseudoword, repeated it and was then asked to omit one letter and pronounce the new pseudoword. In the first round of tests, the child was asked to omit the second letter (i.e., flin-fin), while in the second round of tests it was the second last letter (i.e., rulp-rup). The maximum score was 20.

Spoonerisms

Caravolas and Volin's diagnostic test (2005) was used. The test consisted of ten pairs of monosyllabic pseudowords. The structure of the first two pairs of words was CV, while the structure of the remaining eight pairs was CVC. Pseudowords used in this test and in the previous Phoneme Deletion Test respected Czech phonotactic rules. During the administration of the current test, the child heard a pair of pseudowords and was asked to repeat them, and was then required to transpose the first two letters and say the new word (i.e., nor-sep, sor-nep). The maximum score was 20.

Intelligence

This was measured using Raven's Progressive Matrices (Raven, 2000). The tests were administered individually and without a time limit. The result was a score equivalent to the IQ of the individual.

Statistical Analysis

The dependence of rate (words/minute) and comprehension on the various explanatory variables were studied. Since we observed four phonological variables (word analysis, word synthesis, phoneme deletion, and spoonerisms) we first applied dimensional reduction on all phonological variables (phonological analysis, phonological synthesis, phoneme deletion, spoonerism) to reduce the dimensionality of this effect. Sliced Inverse Regression (SIR) (Li, 1991) with automatic choice of number of slices was applied to generate a smaller number of explanatory phonological variables. SIR generates linear combinations of variables that explain the variability in the response variable, which means that for each response variable (reading speed and comprehension) we generate different reduced variables. The first component of the SIR was used to generate the reduced number of explanatory phonological variables for each response variable, because only the first dimension appears to be significant in all cases. The reduced phonological variable together with grade, gender, IQ, morphological awareness and its interactions were further used in a linear stepwise regression to identify the model with the lowest Akaike Information Criterion (AIC) to examine the best

predictive model for reading speed and comprehension. All statistical analyses were conducted using the R software with the “dr” package for SIR (Weisberg, 2002).

RESULTS AND DISCUSSION

Table 1 presents descriptive statistics.

Table 1. Descriptive statistics – means, standard deviations and ranges

variable	<i>M</i>	<i>SD</i>	range
IQ/Raven’s progressive matrices (standard score)	109	14.8	73-148
Reading quotient RQ (standard score ^a)	98	10.7	81-147
Reading/number of correctly read words per time unit.	78	24.4	20-168
Reading/percentage of errors	2.7	2.8	0-29
Reading comprehension (raw score)	12.4	4.7	1-23
Phoneme analysis (raw score)	18	2.6	9-20
Phoneme synthesis (raw score)	17	3.7	4-20
Phoneme deletion (standard score)	99	16.9	54-121
Spoonerisms (standard score)	105	15.9	57-127
Morphological task (raw score)	53	13.8	19-79

Note: ^a RQ is a standard score that is comparable to the IQ score and is based on the number of correctly read words per time unit.

IQ of our sample was slightly above average compared to the population standard (i.e., 100); the difference was significant ($t = 8.48$, $N = 171$, $t_{.01} = 2.58$). The probable cause was a ceiling effect (skewness = - 0.529). The speed and accuracy of reading did not differ from population norm: the difference between the standard score RQ of our sample and the population norm was not statistically significant ($t = 1.82$, $N = 171$, $t_{.05} = 1.96$); average percentage of errors corresponded to the 5th and 6th stens in the age groups under the study (i.e., 3rd to 6th grade). Average RQ for the 6th, 5th, 4th, and 3rd graders amounted to 102, 97, 97, and 99, respectively; the differences have not reached statistical significance ($F = 1.23$, $df = 170$, $p = 0.302$). The number of correctly read words per minute varied across the age range of our sample; 3rd graders read an average of 62 words per minute, 4th graders of 75 words per minute, 5th graders 84 words per minute, and 6th graders of 105 words per minute. Differences were statistically significant ($F = 18.95$, $df = 170$, $p = 0.000$; 6th graders showed significantly higher performance than all other groups, 3rd graders reached significantly lower performance than all other groups; only the difference between 5th graders and 4th graders was not statistically significant).

To read independently for fun and self-education, a Czech child needs to attain a so-called socially acceptable level (Matejcek, 1998), i.e., at least 60 correctly read words per minute. In our sample, 43 children failed to meet this criterion (i.e., 43/171 → 25%); all 6th graders met this criterion; three 5th graders failed to meet this criterion (i.e., 3/48 → 6%, $M = 51$ words/min, $Me = 49$ words/min); nine 4th graders failed to meet this criterion (i.e., 9/37 → 24%, $M = 53$ words/min, $Me = 52$ words/min); thirtyone 3rd graders failed to meet this criterion (i.e., 31/59 → 53%, $M = 47$ words/min, $Me = 51$ words/min). The average

achievement in comprehension task throughout the sample amounted to 35%; the average achievement 39% in 6th graders, 38% in 5th graders, 32% in 4th graders and 34% in 3rd graders. The differences between the means of the whole sample and different age groups were not statistically significant ($F = 1.72$; $df = 341$; $p = 0.145$).

Phonological skills assessed by standardised deletion and spoonerism tests were within normal limits. The difference between the sample and population mean in deletion test was nonsignificant ($t = 0.537$, $N = 171$, $t_{.05} = 1.96$). The difference between the sample and population mean in spoonerism test was significant ($t = 3.67$, $N = 171$, $t_{.01} = 2.58$). The skills of phoneme analysis and synthesis are assessed as highly valuable for reading (i.e., Torgesen, Wagner, & Rashotte, 1998). A test of phoneme analysis and synthesis is used in the Czech Republic as a clinical tool, without standard scores. Results of the test of phoneme analysis and synthesis in our sample were satisfactory (i.e., 18/20 → 90% analysis achievement and 17/20 → 85% synthesis achievement and corresponded to the speed and accuracy of reading).

The average achievement in morphological awareness test throughout the sample amounted to 62%; (i.e., 53 points out of a maximum of 85). The success rate in 6th graders amounted to 74%; 68% in 5th graders; 60% in 4th graders and 54% in 3rd graders. Differences among groups were statistically significant ($F = 16.08$, $df = 170$, $p = 0.000$). The rise in achievement rate is attributable particularly to school education – Czech pupils acquire morphological knowledge throughout schooling at primary and lower-secondary school, i.e., for nine years.

Reading Speed and Accuracy (the Number of Words Read Correctly per Minute)

From the independent variables entered into the model (Phono R, Morpho, IQ, grade, genders and their interactions: grade x Phono R, grade x Morpho, gender x Phono R, gender x Morpho), the use of Linear Stepwise Regression led to the selection of three variables that best explained reading speed and accuracy: grade, Morpho and Phono R, see Table 2. Of these three variables, phonological awareness (Phono R) had the weakest impact on reading speed and accuracy. However, phonological awareness has fundamental influence on reading speed and accuracy, and our model does not deny the validity of phonological theory about the importance of phonological awareness on reading. Phonological awareness is a condition sine qua non for normal development of reading in alphabetical spelling, and therefore the Czech language environment. The Czech-British team of Caravolas, Volin, and Hume (2005) came to this conclusion by comparing predictors of reading in Czech and English students ranging from 2nd to 7th grade. Using structural equation models, they found that phonological awareness (phoneme deletion, spoonerisms) is a unique predictor of reading (rate, spelling and comprehension). Phonological awareness is comparable in its effects in both respects – English (inconsistent orthography) and Czech (highly consistent orthography), and among all age levels studied. A specific feature of the Czech language is its high transparency (Caravolas, Volin, & Hume, 2005; Matejcek, 1998) and its complicated morphology which, however, Caravolas et al. (2005) did not examine as a potential predictor of reading ability. Both high consistency and difficult morphology places different demands on Czech readers in comparison to English, which is characterised as less phonologically transparent and

morphologically simpler. This is also reflected in our model which focused on morphological awareness as being comparable in its level of influence to phonological awareness.

Table 2. Predictors of reading speed in the final model of a linear stepwise regression

variable	t value	p value
Grade	7.486	$3.88 \cdot 10^{-12***}$
Morpho	5.227	$5.09 \cdot 10^{-7***}$
Phono R	- 1.769	0.078

Note. Grade = 3rd to 6th grade; Morpho = morphological awareness; Phono R = reduced phonological variable. The reduced phonological variable Phono R together with morphological awareness, IQ, grade, gender, and its interactions were used in a linear stepwise regression to identify the model with the lowest Akaike Information Criterion (AIC) to examine the best predictive model for reading speed (words/minute). The final phase of the model included grade, Morpho, and Phono R.

Residual standard error: 16.54 on 167 degrees of freedom. Multiple R-squared: 0.5423, Adjusted R-squared: 0.5341. F-statistic: 65.95 on 3 and 167 df, $p < 2.2 \cdot 10^{-16}$

*** $p < .001$

Our model is a continuation of the trend (and corresponding with findings) observed by Carlisle and Stone (2005) in an English-speaking environment. According to Carlisle and Stone, English students are encouraged towards morphological reading strategy by the phonological transparency of words. Czech, as a highly transparent and morphologically rich language stimulates morphological reading strategy to a greater extent than English. Observations from the English language environment which contribute to the interpretation of our model include the fact that students perceive morphemic units not only in real words but also in pseudowords and that morphological awareness is activated at an early stage of reading, i.e., by orthophonological processing (Deacon & Kirby, 2004; McCutchen et al., 2008). It seems natural, therefore, that in a language environment which, by its nature, encourages students to utilise morphological reading strategy, morphological awareness could have a significant impact on the quality of reading at its lower decoding level and could facilitate reading accuracy.

Because our final model does not contain interaction of morphological awareness with age, we concluded that morphological awareness exercises strong and stable influence on reading speed and accuracy throughout the age range of our sample (from 3rd to 6th grade; i.e., from ages 9 to 12). Similar findings and reasoning applies to phonological awareness – not even in the area of phonological awareness did we find interaction with age in line with the findings of Caravolas et al. (2005). In an English-speaking environment, researchers observed in younger students strong influence of phonological awareness which was balanced by morphological awareness with increasing age (Berninger et al., 2010; Deacon & Kirby, 2004; Mahony et al., 2000). In contrast, in a Czech-speaking environment, the influence of phonological awareness and morphological awareness on reading was equal from an early age. These results could be explained by the different nature of each language which corresponds to different teaching methods when it comes to reading, and different reading development. Czech students are already able to read fluently and comprehend text in the first half of 1st grade, i.e., after 6 months of reading education (Matejcek, 1998).

The present study does not answer the question when morphological awareness begins to exert an effective influence on the development of the Czech reader. Hypothetically, we could

say that at the very beginning of instruction, possibly even in the preschool period. Support for the above hypothesis might be provided by a seven-year follow-up study by Lyster, Lervåg, and Hulme (2016) in the Norwegian language environment, which is relatively close to the Czech environment owing to similar phonological transparency.

The model showed the strong effect age has on reading speed and accuracy. Since we worked with gross scores, this effect is natural and expected. Younger readers are expected to read more slowly and less accurately than older readers who have undergone longer training. At the same time, our sample was selected from normal, typically developing readers attending primary school. Thanks to this, we were able to observe that reading speed and accuracy increased with age.

Comprehension as a Dependent Variable

Linear stepwise regression chose the independent variables entered into the model (Phono R, Morpho, IQ, reading speed, age, gender and their interactions: age x reading speed, gender x reading speed, age x Phono R, age x Morpho, gender x Phono R, gender x Morpho) two variables which best explained reading comprehension: phonological awareness (Phono R) and morphological awareness (Morpho), see Table 3. Phonological awareness is fundamentally important for decoding. The more advanced a reader's phonological awareness is, the greater the likelihood that his or her reading will be more accurate. Morphological awareness allows the reader to identify morphemes (bearers of word meaning). We might expect that in a morphologically challenging environment, such as the Czech language environment, morphological awareness will influence understanding to the same degree as phonological awareness. In the model (Table 3), however, phonological awareness influences understanding more than morphological awareness. This "shadowing" of morphological awareness can be explained by surface reading style. Czech children read less and less, have poorer vocabulary, simpler grammar and style (Zelinkova, 2009). If they have to read, this prevailing style or "zeitgeist" encourages them to read superficially which is characterised by decoding, i.e., speed and accuracy, while deeper understanding of what they are reading eludes them. Connor et al. (2014) mention a similar problem in English-speaking children.

This is when the primary role of morphological awareness is decoding, due to the overlapping of both abilities. This overlap was demonstrated by Goodwin and Ahn in their meta-analytic study (2010). The reciprocal relationship between these two abilities was also reflected in morphophonology (Clin et al., 2009). Thus, our students used morphological awareness mainly for reading on a superficial level, and this was due to morphophonology, and less for reading at a deeper level which required deeper understanding. The influence of age, gender, reading speed and IQ, and the interaction of phonological awareness and morphological awareness with age, gender, reading speed and IQ receded into the background in our model, and were not included in the final model. We cannot therefore say that older and more mature or smarter readers will better use context and understand the semantic depth of the text, compared to younger, less developed and less intelligent readers, who are expected to have more superficial understanding. The aforementioned reading style or "zeitgeist" probably influenced all students, regardless of age, gender, reading speed or IQ. This hypothesis is corroborated by the development of reader's decoding skills, expressed as the number of words read correctly per time unit, and by the development of understanding,

expressed as a gross score. While significant increases in the number of correctly read words per minute were observed in school-age children, increases observed in reading comprehension were low.

In addition to superficial reading style, under utilisation of morphological awareness in reading instruction may be another explanatory variable. Support for this hypothesis might be seen in a study conducted by Lyster et al., (2016) in Norwegian language environment. The authors trained one group of preschool children morphologically, another group phonologically; the third group went through the usual pre-school training in Norwegian kindergarten, i.e., without special training focused on phonological and morphological awareness. The authors then measured reading performance of the children at the end of the 1st and 6th grade of elementary school. They found that morphological training significantly improved reading comprehension in the first and sixth grade, while phonological training did not affect it. If this finding can be transferred to the Czech environment (both languages are phonologically more transparent and morphologically more demanding in comparison to English), it could support our interpretation of a potential in the teaching of reading provided by morphological awareness.

In their study, Lyster et al., (2016) did not find any facilitatory effect of morphological training on reading words in 6th graders, i.e., on the level of decoding. Their findings in this aspect differs from ours, see Table 2, i.e., morphological awareness in our children distinctly contributed to the speed and accuracy of reading. The results of Lyster et al., (2016) are explained by the ceiling effect in reading test, which was created for identification of weak readers. The ceiling effect probably contributed to poorer discriminatory sensitivity of the test. Although our test was not burdened by ceiling effect (degree of skewness in the number of words read correctly per time unit in the entire sample of children equaled 1.64), we arrived at a similar result as Lyster et al., (2016); morphological awareness which had not been systematically trained did not automatically contribute to reading comprehension. The authors do not explain their findings by a superficial reading style or insufficient application of morphological awareness in the teaching of reading. Given the similarity of the findings and the similarity of the two languages, Norwegian and Czech, we believe that the result could be – besides the ceiling effect – also affected by the superficial style of reading, or reading didactics.

Table 3. Predictors of reading comprehension in the final model of a linear stepwise regression

variable	<i>t</i> value	<i>p</i> value
Morfo	1.519	0.131
Phono R	- 4.040	$8.1 \cdot 10^{-5***}$

Note. Morpho = morphological awareness; Phono R = reduced phonological variable. The reduced phonological variable Phono R together with morphological awareness, IQ, reading speed, grade, gender, and its interactions were used in a linear stepwise regression to identify the model with the lowest Akaike Information Criterion (AIC) to examine the best predictive model for reading speed (words/minute). The final phase of the model included Morfo and Phono R.

Residual standard error: 4.497 on 168 degrees of freedom. Multiple *R*-squared: 0.1518. Adjusted *R*-squared: 0.1471. *F*-statistic: 15.04 on 2 and 168 *df*, *p*-value: $9.82 \cdot 10^{-7}$

*** *p* < .001

Explicit vs. Implicit Understanding and Reading Quietly vs. Aloud

In the present study, we tested explicit understanding, i.e., literal understanding, which is connected to information explicitly mentioned in the text and which is immediately processed while reading. Implicit understanding is associated with the ability of the reader to “read between the lines”, connect data with other information from other sources, as well as their own experience. Implicit understanding benefits from the context. Implicit understanding represents a deeper level of understanding and usually requires an interval in which the text is processed or read repeatedly. Kucharska et al. (2015) studied conditions under which understanding develops in 1st to 4th Czech graders. A slight prevalence of explicit over implicit understanding was found in continuous texts with contextual support when reading aloud; differences in the surveyed age range were not statistically significant. A significant increase in the score of implicit understanding was detected when 3rd graders were compared with 4th graders. Kucharska et al. suggested that implicit understanding compared with explicit started later. These findings by Kucharska et al. (2015) correspond to or support our findings presented in Table 3, and their explanation by superficial reading style, aimed at explicit understanding. The children in our sample read a story and read it aloud. Immediately after reading they were asked questions to check understanding. The variable best explaining their understanding was the phonological skill, despite the hypothetical predominance of the morphological skill, which would enable children to get semantically deeper. Kucharska et al. (2015) also observed a tendency towards superficial, explicit understanding in comparable reading conditions. When considering reading continuous text silently, Kucharska et al. (2015) found superiority of implicit understanding as early as the 3rd year of primary school. Prior et al. (2011) only observed this phenomenon in an English-language setting in older pupils: 1st to 5th graders benefit more from reading aloud. Starting with 7th graders, pupils begin to benefit more from reading quietly. The reason of this shift might be the nature of both languages: Czech is phonologically-friendly and therefore allows deeper understanding even to younger readers. In our study, we did not manipulate the mode of reading (loud vs. quiet). According to the findings by Kucharska et al. (2015) we could expect that this mode could affect the outcome presented in Table 3, increasing the effect of morphological variable on understanding. The favourable effect of silent reading on comprehension should occur, in accordance with Kucharska et al., especially in older children under study, i.e., 5th and 6th graders. Our final model should then reflect the interaction of morphology and age, but it did not. Therefore, we think that the orientation towards superficial reading style was stronger than the effect of reading mode (loud vs. quiet).

Reading style focussing on superficial vs. deep understanding is not only a neuropsychological function dependent on the development of the brain, but also on the conditions under which the pupil is educated. It would therefore be interesting to manipulate experimentally conditions of learning and set aside an experimental group within our sample that would go through the teaching of reading focussing on implicit understanding. In our sample, only the method of teaching reading was broadly monitored, i.e., all the children learned to read using the analytic-synthetic method that prevails in current Czech schools. Owing to the strong effect of morphological awareness on reading from at least the third year of elementary school onwards observed in our study, we deduce that Czech children are ready for a deeper comprehension earlier than children in the Anglo-Saxon environment, at least from the 3rd grade, possibly even from the 2nd year. This assumption could be verified experimentally. Our study may also be perceived as an incentive for further extension of

morphological training in kindergarten. Phonological training dominates in educating Czech preschool children, probably under the influence of the phonological theory. Preschool education could thus effectively shape predisposition to reading. Neuropsychological issues are unclear – i.e., in what stage of neuropsychological development is the preschool child's brain ready for systematic morphological exercises to be beneficial to the child and not a burden. This issue will have to be studied specifically for the Czech language environment, which is morphologically particularly challenging. However, it is the task for further research.

Prediction of Reading

In the present study, the relationship between morphological and phonological awareness in the Czech language environment was examined. The study revealed that the influence of morphological awareness on reading can be equivalent to the influence of phonological awareness. The limiting factor of our study is the absence of RAN-variable. Furnes and Samuelsson (2010) compared the predictability of RAN and phonological awareness in more transparent orthography (specifically for Norwegian and Swedish children) vs. less transparent orthography (US/Australian children). They examined phonological awareness and RAN in preschool children and observed them until the second year of elementary school. The authors observed that predictability of phonological awareness in a sample of Scandinavian children was limited to the first year of elementary school, while in the English-speaking children it persists into the 2nd year. RAN predictability is reliable in the 1st and 2nd year in both types of orthography, the more transparent and the less transparent. Their study is limited by the absence of morphological awareness. In agreement with our findings, we could assume that morphological awareness will have a similar role as RAN in more transparent orthography, i.e., it will be a significant predictor of reading and its predictability will not fall in contrast with phonological awareness. The conclusions of Furnes and Samuelsson are corroborated by the international study ELDEL (Caravolas et al., 2012), which compared the predictability of phonological awareness, knowledge of sounds and letters, and their correspondence with RAN in beginning readers of four different types of orthography (English, Spanish, Czech, Slovak). The authors found that the effect of predictors on initial reading was comparable regardless of the language environment. Unfortunately, even this study did not work with morphological awareness, and did not compare its predictability with RAN. According to our findings, it is possible to assume that the inclusion of morphological awareness could change their resulting model of initial reading, in which phonological awareness, orthographic knowledge and RAN contribute roughly equally. In languages with more transparent orthography and demanding morphology (Czech, probably Slovak or even Spanish), morphological awareness could be greater than in English-speaking children.

Normal vs. Subnormal Reading

An Austrian-British team compared Austrian and British dyslexics (Landerl, Wimmer, & Frith, 1997). German is considered a consistent orthography in contrast with English, which is significantly inconsistent. The authors presented the dyslexics with a test, which consisted of very closely similar words in both languages, i.e., jung – young, Sommer – summer, attraktiv – attractive. The test also included pseudowords, which are considered in an English language environment to be particularly useful for testing phonological skills, because they bear no meaning. Dyslexics can therefore not rely on semantics and must rely on phonological clues. The results showed that English dyslexics had massive difficulties with

phonological coding in contrast with Austrian ones. When reading, they made significantly more errors, both in meaningful words and pseudowords. In contrast, Austrian dyslexics were characterised by relatively high accuracy (both in reading real words and pseudowords) and their reading problems consisted in a slow reading pace. From the findings by Landerl et al., (1997) we can conclude that dyslexics in transparent German orthography, and generally in any transparent orthography, which includes Czech, have fewer difficulties with phonological clues, by means of which the words are processed. The requirement of phonological processing in a transparent orthography is easily achievable for most children; the normality of reading is accessible for most children in this orthography. Therefore, the relationship between phonological processing and reading is probably less clear in transparent orthography. It's very similar to an extremely easy performance test: If all children manage it, the test loses its distinctive ability to differentiate between below-average, average and above-average individuals. It is undesirable in the case of a test, whereas in the case of orthography it is, conversely, the desired state.

Our findings suggest that the importance of morphological and phonological skills is comparable. We can assume that the morphological features of dyslexia are likely to be less pronounced in the English-language environment, while in the Czech-language environment they will be highlighted by the nature of the Czech language. We can even expect a new type of dyslexia to emerge – besides the repeatedly confirmed phonological type it may be the “morphological” type, specific to a particular language and prompted by the specific difficulty of the given language environment. This hypothesis may be confirmed by fMRI findings. For example, Arredondo, Ip, Ju Hsu, Tardif, and Kovelman (2015) found that brain regions, which had previously been thought to serve only phonological skills, were activated in solving morphological tasks. If dyslexia is neurobiologically uniform and its manifestations are formed by the environment, as Arredondo et al. (2015) or Paules et al. (2001) suggested, then in a phonologically demanding and morphologically undemanding environment in which English-speaking dyslexics develop, morphological deficits recede into the background, while phonological deficits are getting into the foreground. Conversely, in the Czech language environment, morphological deficits in dyslexics can be striking.

CONCLUSION

In the Czech language environment, which is characterised by morphological complexity and phonological simplicity, morphological awareness affects reading development in 3rd to 6th graders of elementary school at the same level as phonological awareness does. This effect is independent of age, gender and IQ. It occurs at both decoding and understanding, where its effect is weaker than expected – probably due to the superficial reading style.

The study showed the important features of literacy – morphological awareness which still stands outside the scope of interest of teachers and psychologists in the Czech Republic and which is not sufficiently exploited and cultivated for the development of reading. It is paradoxical because the Czech language environment is particularly suitable for training morphological awareness. High level of phonological awareness encourages readers to employ a morphological strategy, enabling deeper penetration into the meaning of orthographic record. If superficial learning style is to be superseded, then focus on

morphological strategies in reading and morphological training represents one of the possible ways.

Our findings can be significant for diagnosis and training prerequisites of reading and predicting reading in preschoolers. In addition to existing cognitive variables (phonological awareness, IQ, vocabulary, working memory, RAN, knowledge of letters and orthographic processing) morphological awareness comes into play as a potentially important predictor as well as the reading prerequisite that in the Czech environment still stands in the background of interest in reading training.

The conclusion of the present study can be applied not only to typically developing readers, but also readers with impaired reading and spelling.

SUPPLEMENTARY MATERIAL

In morphology, we can distinguish three basic processes: inflection, derivation and compounding. The most commonly used process in Czech is inflection. Derivation is also of significant importance but compounding does not play any vital role (in contrast to German). In Czech, as in Finnish, inflection is very complex. This means that in Czech there is a prevalence of inflectional words which change their form depending on context, quite unlike non-inflectional words which do not change form. Inflectional words are names (nouns, pronouns and numbers), adjectives and verbs. Invariant words include adverbs, prepositions, conjunctions, particles and interjections. During inflection (i.e., the changing of the form of a word), one morpheme belongs to several grammatical categories at once; typically, it occurs as a word ending. During inflection (conjugation/declination), morphemic endings usually carry grammatical meaning, i.e., gender, number and case. In Czech, we distinguish seven cases (nominative, genitive, dative, accusative, vocative, locative, instrumental), dual number (singular and plural; only some nouns have dual form) and triple gender (masculine, feminine and neutral). In the masculine gender, we distinguish between animate and inanimate.

For each name, we must recognise its gender, number and case. Since names are distinguished according to seven cases in dual numbers, this means we have 14 forms for each word. Together, the shapes of one word constitute what is known as the morphological paradigm of the word. There are many such paradigms in Czech which can be divided into three categories: noun declension, pronoun declension and mixed declension. There is a different set of morphological paradigms for each type of declension. Noun declension is typical for nouns and has a total of fourteen different morphological paradigms. For each of the three noun genders, we use a different morphological paradigm: four morphological paradigms for the feminine, four morphological paradigms for the neuter, and six morphological paradigms for the masculine, of which four are masculine animate and two are masculine inanimate. In addition, there are similar sub-paradigms which differ from main morphological paradigms in the endings of some forms. Mixed declension is typical for adjectives, while pronoun declension applies only to pronouns. Each of these declension types has two morphological paradigms. These two declension types have a different system of morphological paradigms to noun declension. In noun declension, each noun has only one possible noun gender. On the other hand, in mixed and pronoun declension, each morphological paradigm has three variants according to gender. During the conjugation of

verbs, the ending expresses person and number. In some types of expressions, however, Czech – like English – uses the auxiliary verb to be; compared to English, this verb is more inflectional. For the conjugation of verbs, Czech has fourteen morphological paradigms which are characterised by different word endings. In Czech, there are imperfective verbs which express that an activity is unlimited in terms of time (i.e., to do something continuously) and verbs perfective that express an action is bound by time. The change from imperfective and perfective is performed using different types of derivatives. In Czech, we can classify verbs according to verbal aspect as well as multiplicity-iterativity, which is realised using derivatives. Aside from inflection, derivation is also widely applied in Czech. Many words are derived from others with the help of suffixation, prefixation and stem alterations (infixation). The most common Czech words that serve as a foundation for derivation are nouns and verbs. Derivation usually causes sound changes and leads to new forms of verbs and nouns. Derivation is also used to express the aspectual relations of verbs and iterative relations of verbs. Derivation can also lead to the formation of semantic variations. Derivation of most adjectives and adverbs leads to the formation of the 2nd and 3rd person singular and plural forms.

Chapter 21

THE RELATIONSHIP BETWEEN VOCABULARY AND READING DEVELOPMENT

Irene Cadime^{*}

Research Centre on Child Studies, University of Minho,
Braga, Portugal

ABSTRACT

Research has indicated that vocabulary depth and breadth are strongly correlated with reading comprehension and, consequently, with academic achievement. Recent research has demonstrated that vocabulary can even predict achievement up to 10 years later. Some theoretical models, such as the simple view of reading (Hoover & Gough, 1990) or the multicomponent view of reading (Cain, 2009) have received extensive empirical support and provided a clear insight into the relationship between reading comprehension and other linguistic variables, including vocabulary. In the context of these frameworks, studies have explored if vocabulary has a direct effect on reading comprehension or if the relationship between both variables is mediated by word reading and listening comprehension. The results generally seem to support a mediation effect; however, more studies are needed in different orthographies and grade levels. Additionally, results of other studies have indicated the existence of reciprocal relationships between the development of vocabulary and different reading abilities, as well as between the development of vocabulary and the comprehension of oral language. The implications of these findings for the design of interventions and for the planning of reading instruction are discussed.

Keywords: vocabulary, reading comprehension, listening comprehension, word reading

1. INTRODUCTION

Children demonstrate some understanding of words and their meaning since early childhood. Typically, children produce their first words around their first birthday, but at this stage, they already show signs of comprehending several words; that is, their receptive vocabulary is much larger than their expressive vocabulary (Cadime, Silva, Santos, Ribeiro, & Viana, 2017; Jalongo & Sobolak, 2011; Kern, 2007). Around the children's second birthday, they are already capable of producing, on average, more than 300 words (Fenson et al., 2007). Furthermore, the children's vocabulary continues to grow in the subsequent years. Some studies on school-age children have indicated that they learn, on average, 2000 new words each year (for a review, see Nagy & Scott, 2000). However, the number of words produced is only one indicator of vocabulary. Vocabulary refers to the knowledge of words, the words' meanings, and the concepts associated with those meanings (Aarnoutse, van Leeuwe, Voeten, & Oud, 2001). In this sense, a distinction between vocabulary depth and breadth has been made in research (Cain, 2010). Vocabulary breadth refers to the number of lexical representations of the sound patterns of words within the lexicon (i.e., lexical entries), whereas vocabulary depth refers to the extent or quality of the semantic representations of word meanings (Ouellette, 2006; Swart et al., 2017). Lexical development is a continuous and incremental process, with phonological, orthographic, and semantic knowledge being continuously extended (Li, Farkas, & MacWhinney, 2004; Nagy & Scott, 2000).

Vocabulary seems to assume special importance for reading comprehension development, given that it is needed to process the meanings of words and phrases in the text. This chapter provides an overview of the complex interrelationships between vocabulary and different reading abilities, and discusses the mechanisms that underlie these relationships.

2. THE RELATIONSHIP BETWEEN VOCABULARY AND READING SKILLS

Several studies have indicated that children with reading disabilities show vocabulary deficits (Colenbrander, Kohnen, Smith-Lock, & Nickels, 2016; Nation & Snowling, 1998; Stothard & Hulme, 1992). Similarly, other studies have found that poor readers have lower expressive and productive vocabulary than do good readers, even after controlling for IQ differences (Kail & Leonard, 1986). Similarly, some studies assessing the effectiveness of interventions have suggested that promoting vocabulary leads to some improvement in reading comprehension (e.g., Bos & Anders, 1990).

The final goal of reading is to comprehend. Reading comprehension can be defined as the ability to construct meaning from written language (Snow & Sweet, 2003). A similar idea underlies the construction-integration model by Kintsch and colleagues (Kintsch, 1998; Kintsch & Rawson, 2005; Kintsch & Van Dijk, 1978). According to this model, the goal of comprehension is to construct a coherent mental representation of the situation described by the text, which is called the situation model of the text. The construction of the situation model requires the processing of two lower levels: (a) surface code, which refers to the linguistic unities (words and phrases) in the text, and (b) textbase representation, which refers to the construction of a representation of the elementary propositions expressed by the text,

i.e., includes the linguistic structure of the text and its meaning (Kintsch & Rawson, 2005). Thus, the situation model is a more abstract representation that includes not only the content of the textbase representation (which, in turn, is based on the surface code), but also the readers' previous knowledge (Cain, 2009; Graesser, Singer, & Trabasso, 1994). Vocabulary assumes an important role in the construction of textbase representation, given that the construction of the elementary propositions expressed by the text requires the lexical processing of words and sentences.

Not surprisingly, correlational studies have demonstrated that the students' vocabulary breadth and depth are associated with their reading comprehension levels (Aarnoutse et al., 2001; Droop & Verhoeven, 2003; Kim & Pallante, 2012; National Institute of Child Health and Human Development, 2000; Ouellette & Shaw, 2014; Ribeiro, Cadime, Freitas, & Viana, 2016; Ricketts, Nation, & Bishop, 2007; Santos et al., 2016; Swart et al., 2017; Torgesen, Wagner, Rashotte, Burgess, & Hecht, 1997; Verhoeven, 2000). However, the association seems to be stronger in more advanced grades, a result of which was obtained in not only deep orthographies (e.g., Ouellette & Beers, 2010), but also orthographies of intermediate depth (e.g., Fernandes, Querido, Verhaeghe, Marques, & Araújo, 2017; Seigneuric & Ehrlich, 2005). This finding was interpreted as the result of the progressive automatization of reading through experience, which allows other skills to become more important predictors of reading comprehension. In other words, word reading is one of the best predictors of reading comprehension in the initial years of reading acquisition, given that inaccurate or slow word reading severely affects the students' comprehension levels (Adlof, Catts, & Little, 2006; Francis, Fletcher, Catts, & Tomblin, 2005; Oakhill, Cain, & Bryant, 2003). Additionally, because word reading is not automatized in these initial years, it demands a heavy processing capacity, thus leaving less cognitive resources for higher order comprehension processes (National Institute of Child Health and Human Development, 2000; Perfetti, 1985; Stanovich, 2000). As reading becomes more automatic, linguistic skills such as vocabulary and listening comprehension become stronger predictors of the students' text comprehension (Catts, Hogan, & Adlof, 2005; Gough, Hoover, & Peterson, 1996; Tilstra, McMaster, Van den Broek, Kendeou, & Rapp, 2009). Thus, the relative importance of different linguistic skills on reading comprehension changes during the course of development.

The importance of vocabulary for reading comprehension development has also been demonstrated in longitudinal studies. The vocabulary level of children by the time they enter school is an important predictor of their level of reading comprehension skills in their subsequent years (Kim, Petscher, Schatschneider, & Foorman, 2010; Muter, Hulme, Snowling, & Stevenson, 2004; Verhoeven & van Leeuwe, 2008). Seigneuric and Ehrlich (2005) assessed longitudinally a group of French students from grades 1 to 3, by using measures of reading comprehension, vocabulary, working memory, and non-word reading. Their results indicated that the vocabulary level in grade 1 was the most important predictor of reading comprehension in grade 3. Similarly, in a study with Dutch children, Aarnoutse, Van Leeuwe, and Verhoeven (2005) found that children's vocabulary in the last year of kindergarten was one of the main predictors of reading comprehension in grade 2. However, the long-term predictive power of vocabulary seems to be even stronger than expected. Using data from a large-scale study conducted in the United States, Lee (2011) found that the expressive vocabulary of children aged two years old can predict their reading comprehension levels up to nine years later. Similarly, a recent study with Danish children indicated that the

vocabulary level at an age as early as 16 months old can predict reading comprehension ten years later (Bleses, Makransky, Dale, Højen, & Ari, 2016).

Given the importance of lexical processing for the construction of textbase representation, vocabulary has been associated with not only high order comprehension processes, but also low-level word reading and text reading fluency (Ouellette, 2006; Tobia & Marzocchi, 2014; Van Weerdenburg, Verhoeven, Bosman, & van Balkom, 2011; Verhoeven, van Leeuwe, & Vermeer, 2011). Studies have argued that the lexical representations that a reader possesses act like facilitators in word reading; thus, the higher the number of lexical entries and the higher the extent of the mental representations in memory, the more successful and faster the word identification process will be (Perfetti, 1998). Furthermore, other researchers have suggested that the mechanism underlying the relationship between vocabulary and word reading abilities is also related with the phonological coding of words; that is, the degree to which the sound patterns of words are specified in the lexicon influences the phonological awareness levels of the children, and consequently, influences their ability to map correspondences between graphemes and phonemes, and read words (Elbro, Borstrøm, & Petersen, 1998).

In conclusion, not only is vocabulary a fair indicator of children's reading abilities at any time but it is also a long-term predictor, and these findings have been observed in several different alphabetic orthographies. However, the debate persists on whether the relationships between vocabulary and reading are direct or indirect and whether these relationships are unidirectional or reciprocal.

2.1. Is Vocabulary a Direct or an Indirect Predictor of Reading Comprehension?

As mentioned before, research has consistently found an association between vocabulary (breadth and depth) and reading comprehension. However, the question of whether vocabulary contributes directly or indirectly to reading comprehension has received some attention.

According to a multicomponent view of reading comprehension (Cain, Oakhill, & Bryant, 2004), several skills contribute directly to the comprehension levels that the readers can achieve when they read a text. Vocabulary is among those skills. Results of studies that found a direct relationship between vocabulary and reading comprehension provide empirical support for this theoretical model (e.g., Seigneuric & Ehrlich, 2005).

The simple view of reading (SVR; Hoover & Gough, 1990) is another framework of reading comprehension and perhaps one of the most influential. According to this framework, reading comprehension is the product of two main skill components: word recognition and listening comprehension. The simple view of reading has received extensive support in studies conducted on readers of different orthographies, including deep and transparent orthographies (Adlof et al., 2006; Cadime, Rodrigues, et al., 2017; Florit & Cain, 2011; Joshi & Aaron, 2000; Joshi, Tao, Aaron, & Quiroz, 2012; Megherbi, Seigneuric, & Ehrlich, 2006; Tilstra et al., 2009; Tobia & Bonifacci, 2015). However, the SVR has also received some criticism because it fails to include, explicitly, several other skills related to reading comprehension, such as vocabulary (Braze et al., 2015; Braze, Tabor, Shankweiler, & Mencl, 2007). In fact, the concept of listening comprehension refers to oral language and linguistic

skills in its broad sense; therefore, listening comprehension could be understood as a dimension that encompasses oral vocabulary (Protopapas, Mouzaki, Sideridis, Kotsolakou, & Simos, 2013; Protopapas, Simos, Sideridis, & Mouzaki, 2012). Nonetheless, this assumption has not received much empirical support. For example, Ouellette and Beers (2010) administered measures of phonological awareness, decoding, irregular word recognition, listening comprehension, vocabulary, and reading comprehension to a sample of English-speaking Canadian students in grades 1 and 6. In the study, listening comprehension was measured by a task in which the students were required to read stories and answer questions about the stories. They found that, for the older students, vocabulary explained the unique variance in reading comprehension, even after controlling for the remaining variables (including listening comprehension). This finding suggests that oral vocabulary explains the variance in reading comprehension over and above listening comprehension and, therefore, should be analysed as a distinct construct.

Other scholars (e.g., Kim, 2015) have suggested that, in this framework, the relationship between linguistic skills, such as vocabulary, and reading comprehension is assumed to be mediated by listening comprehension and word reading. Mediation effects require that not only do the mediators (listening comprehension and word reading) predict the outcome variable (reading comprehension), but also that the predictor (in this case, vocabulary) is related with the mediators. In fact, several studies have provided evidence to support the existence of a relationship not only between children's vocabulary and word reading (e.g., Mitchell & Brady, 2013; Ouellette, 2006), but also between vocabulary and listening comprehension (e.g., Florit, Roch, Altoè, & Levorato, 2009; Kim & Phillips, 2014; Tompkins, Guo, & Justice, 2013; Viana et al., 2015). In this context, the relationship between vocabulary and listening comprehension, which is understood as the ability to construct meaning from oral language (Gilakjani & Ahmadi, 2011), is quite intuitive, given the importance of knowing words and their meanings to understand oral messages. In fact, vocabulary is a foundational skill that is used also for constructing the propositions needed for building the situation model at the discourse level, which is the goal of listening comprehension.

Given these findings, a small number of studies tested the hypothesis that the two components of the SVR (word reading and listening comprehension) mediated the relationship between vocabulary and reading comprehension processes. Vellutino, Tunmer, Jaccard, and Chen (2007) conducted a study with English-speaking children in grades 2-3 and grades 6-7, and found that listening comprehension and word reading completely mediated the relationship between semantic knowledge (i.e., vocabulary) and reading comprehension. Similar results were obtained in another study conducted in the United States with students from grades 1 to 3: In all three grades, vocabulary had an indirect effect on reading comprehension via both word decoding and listening comprehension (Cain, Catts, Hogan, & Lomax, 2015). A similar finding was also obtained by Kim (2015) in a sample of Korean-speaking kindergarten children (in Korea, kindergartners typically receive some reading instruction) in which listening comprehension and word reading completely mediated the relation of language and cognitive skills to reading comprehension. Kim (2015) also found that vocabulary was not only directly related to listening comprehension, but also indirectly via comprehension monitoring and the theory of mind skills.

Taken together, the findings of these studies supported empirically the mediation hypothesis in the SVR, thereby suggesting that the relationship between vocabulary and the

meaning construction from written language (i.e., reading comprehension) is mediated by oral language comprehension abilities and by low-level processes of word recognition. However, more studies on different orthographies and grade levels are needed.

2.2. Vocabulary and Reading Skills: Is the Relationship Reciprocal?

Another related issue is whether the relationship between vocabulary and reading is reciprocal. As mentioned before, vocabulary has been consistently found to be a significant predictor of reading skills and listening comprehension. However, given the fact that the sources of vocabulary acquisition can be varied and that vocabulary can be acquired through reading or through oral language (Gellert & Elbro, 2013; Nagy & Scott, 2000; Perfetti, Landi, & Oakhill, 2005; Verhoeven et al., 2011; Zhang et al., 2017), it is plausible to assume that reading skills and oral language comprehension are also predictors of the quantity and quality of the children's lexical representations. In fact, the results from longitudinal studies have indicated that the development of vocabulary and reading abilities is interrelated. This is exemplified in a longitudinal study that assessed Dutch children between grades 1 and 6: On the one hand, vocabulary predicted later word reading in grades 1 and 2, whereas, on the other hand, word reading predicted later vocabulary levels, although this second effect was only observed from the second grade onwards (Verhoeven et al., 2011). Verhoeven et al. (2011) suggested two possibilities to explain the finding that word reading had no effect on vocabulary at the beginning phase of reading instruction, but it had a significant effect in more advanced stages. The first possibility was that, at the early stages of reading instruction, the words used in the reading materials might have been very simple and common; therefore, those words are probably already part of the children's lexicons, and the reading activities do not contribute to increasing children's vocabulary (Verhoeven et al., 2011). The second hypothesis was that only in the later stages of reading acquisition, the automatization of word reading releases enough cognitive resources to allow the readers to process meanings and increase the quantity and quality of their lexical representations (Perfetti, 1998). Accurate and fast reading is particularly important when children encounter new words during text reading and need to determine their meaning using context. In fact, text reading fluency can also be a predictor of vocabulary in different age stages. For example, in a recent study with Portuguese students, Fernandes et al. (2017) found that text reading fluency predicted vocabulary in first and sixth graders.

However, the reciprocal relationships between vocabulary and reading are not limited to the low-level reading skills and have also been found for comprehension processes. For example, Verhoeven and van Leeuwe (2008) conducted a longitudinal study with Dutch children, who were assessed every year in grades 1 to 6. Using cross-lagged panel model analyses, they found that the relationships between vocabulary and reading comprehension were reciprocal across this time interval. Therefore, they concluded the following:

The more one reads, the more one can deduce word meanings from the surrounding text and, conversely, the more one comprehends, the more one's vocabulary may grow. In any case, reading comprehension can only be successful when word forms are readily identified and word meanings are easily accessed, which places considerable demands on the underlying linguistic capacities of the child (Verhoeven & van Leeuwe, 2008, p. 408).

A reciprocal relationship was also found between vocabulary and listening comprehension. This finding suggests that the more information a child hears (e.g., stories or conversations), the more words (and their meanings) the child can learn. In turn, the more words the child knows, the higher the comprehension levels that the child obtains from oral information. However, it must be noted that the vocabulary measures used in both studies involved not only vocabulary but also reading skills: In each item, the children read one sentence where a target word was underlined, and the task was to select an alternative for the target word from a list of four options. As a consequence, this feature of the measure could be partially responsible for the observed results.

CONCLUSION

To summarize, the research on the relationship between the development of vocabulary and reading abilities seems to support the so-called lexical quality hypothesis (Perfetti & Hart, 2001). According to the lexical quality hypothesis, comprehension is affected by not only the number of available lexical entries, but also the quality of the reader's lexical representations, including the semantic, syntactic, and morphological features of the words (Perfetti & Hart, 2001; Perfetti & Stafura, 2014). Although this framework has been used to explain the relationship between vocabulary and reading comprehension, research has indicated that it can also be used to explain the relationship between vocabulary and listening comprehension, given that both types of comprehension require the same processes of meaning integration (Kim, 2015; Kintsch & Van Dijk, 1978).

The results of recent studies, which suggested that the chain of influence of vocabulary on reading comprehension appears to be via listening comprehension and word reading, as well as the results that demonstrated the existence of reciprocal relationships between the development of vocabulary and reading skills, should not be ignored. If, on the one hand, familiarity with the words in a text can facilitate reading while, on the other hand, accurate and fast reading and skilled comprehension of a text can lead to vocabulary growth, then all these dimensions should be considered together when planning reading instruction in mainstream classes and when designing intervention programs for children with reading disabilities. Emphasis should be placed not only on oral language skills and vocabulary, or solely on the teaching of basic reading skills; instead, a broader approach that includes all components is necessary (Dickinson, Golinkoff, & Hirsh-Pasek, 2010; Torgesen, 2002). Reading instruction should promote deeper levels of processing, and intensive vocabulary instruction should be embedded in the reading activities. In this sense, teachers should plan instruction activities to expand the lexical repertoire of the children, by using diversified texts that include not only words that are familiar to students, but also words that are unknown to students. The exploration of these texts, which can be written or orally presented, should also include, when possible, activities that help students develop metacognitive strategies to deal with unknown words and unknown meanings when reading a text (Ribeiro et al., 2015). The diversity of activities is also important. The more encounters a child has with a word (in its oral and written forms), and the more varied the contexts where the child sees or hears the word, the more likely it is that the child will learn the word and process it deeply in semantic terms (Beck & McKeown, 1991).

Chapter 22

INCIDENTAL VOCABULARY LEARNING THROUGH NEGOTIATION FOR MEANING IN SYNCHRONOUS COMPUTER-MEDIATED COMMUNICATION

Sarah H. J. Liu*

Department of Applied English, Kainan University,
Taoyuan, Taiwan

ABSTRACT

In the past few decades much research attention has been given to determining the effects of incidental vocabulary learning through negotiation for meaning on second or foreign language (L2/FL) vocabulary gains in a face-to-face (F2F) environment since vocabulary knowledge in L2 or FL is considered an important skill in order to have effective communication skills or good academic performance. In this line of inquiry, the nature of technology- or computer-mediated communication makes enhanced incidental learning feasible. This article aims to discuss relevant underlying theories and review previous empirical studies on language learning in both F2F and synchronous computer-mediated communication (SCMC).

Keywords: synchronous computer-mediated interaction, incidental vocabulary learning, second or foreign language learning

INTRODUCTION

Computer-mediated communication (CMC) is viewed as a useful tool to enhance second or foreign language learning (L2 or FL) since it promotes form-focused interaction (Hung & Higgins, 2015), allows learners to collaborate with each other to co-construct knowledge (Lee, 2002, as cited in Yilmaz & Granena, 2010), and most essentially provides learners with ample opportunity to interact with speakers of the target language or to practice the language

* Corresponding Author Email: sarah.hjliu@gmail.com.

without a limit to time and place. Moreover, CMC permits language practitioners or researchers to observe learners' language development in order to meet effective pedagogical agenda. In particular, synchronous text-based communication not only helps language learners to produce longer stretches of messages but also lowers their anxiety when encountering communication breakdowns.

Previous studies have emphasized that comprehensible input, the interaction hypothesis (Long, 1996), will be reinforced through clarifying words' meanings in the target language. The negotiated interaction has been deeply rooted in the Vygotsky's zone of proximal development (ZPD, 1978). ZPD emphasizes that for an individual acquiring knowledge the learner's interpsychological and intrapsychological efforts are required, thus implying that she initially interacts with her interlocutor(s) and then internalizes the learned components with her existing knowledge.

One research line has observed how learners working collaboratively in an F2F or SCMC environment employ interactional or communication strategies to solve linguistic difficulty; this suggests that the strategic processing affects form acquisition and that the benefit of using SCMC permits learners to look at the negotiated form on screen. Following this, the review paper will address the issues of L2/FL incidental learning, interactional strategy use, collaborative learning, and using SCMC/CMC tools for L2/FL learning.

INCIDENTAL VOCABULARY LEARNING IN L2/FL

Vocabulary knowledge has long been considered a building block of effective communication in L2 or FL. Without a sufficient vocabulary capacity, an individual will be expected to encounter difficulties in conveying his/her meaning or understanding what has been heard or read in the target language. In order to effectively communicate with others or comprehend texts, the learner may be expected to read or use the language substantially. Indeed, incidental learning underscores the importance of form-focused instruction (FFI), the overriding purpose of which is to facilitate form acquisition during planned or incidental instructional activities within a classroom (Ellis, 2001). The benefits of incidental vocabulary learning are to foster learners' reading strategy use, for example, establishing a conceptual framework to filter what is an irrelevant meaning of new vocabulary, inferring unknown words' meanings from contexts, and helping learners to elaborate on the new encounter while reading (Hulstijn, Hollander, & Greidanus, 1996).

Many of the previous studies examined the impact of incidental learning through reading or listening texts on linguistic gains, for example, Godfroid et al. (2017), and Hulstijn et al. (1996). In their study, Godfroid et al. (2017) investigated whether learners decreased processing time of new lexical items when they were frequently exposed to those items during L1 and L2 reading. Through an eye-tracking device, their results suggest that the participants who repeatedly encountered the target words in different contexts while reading tended to spend less time decoding the words.

However, other studies investigating incremental learning through negotiation between native speakers (NSs) and non-native speakers (NNSs) (e.g., Long, 1983; McDonough, 2005; Varonis & Gass, 1985), between teachers and students (Lyster, 1998), or between non-native speakers (e.g., Campillo, 2003), suggest that a negotiated form drawn from feedback provided

by learners' interlocutors may be inductive to the development of the language. Those studies have also given rise to the extent to which types of corrective feedback affect language gains; for example, repeating an error and providing a correct form was found to be more effective than explaining an incorrect form to acquire the target item (Campillo, 2003). NNS-NNS interaction was more likely than NS-NNS interaction to facilitate longer exchanges of utterances in a nonthreatening environment (Varonis & Gass, 1985). Instead of providing learners with correct forms or recasts, prompts that required the learners to repair their own errors tended to promote more accuracy in usage of tenses (Yang & Lyster, 2010).

In Newton's (2013) study, communication tasks, such as information gap and opinion gap, helped learners to engage in incidental vocabulary learning, by paying attention to their linguistic errors and attending to correct forms provided by their peers when they collaborated in solving lexical problems. In terms of the rate of learning new vocabulary, words that were negotiated were more likely learned than those that were not negotiated. Furthermore, he points out that a learner was required to have more encounters while learning new vocabulary through reading; however, a learner who negotiated new vocabulary was likely to learn with few encounters.

INTERACTIONAL OR COMMUNICATION STRATEGY USE IN L2/FL LEARNING

Strategy use enables learners to overcome language insufficiency as it is deemed to be essential to be acquired by the learners. Among many possible strategies, those employed by conversation interlocutors can be described as interactional or communication strategies (CSs) and the strategies can be applied in a synchronous (e.g., text/voice/video chat), face-to-face environment, or asynchronous setting (e.g., email exchanges). Theoretically speaking, CS from a socially interactional point of view is said to be the mutual attempt of two interlocutors to agree on a meaning in situations where requisite meaning structures are not shared (Tarone, 1983; Tarone, Cohen, & Dumas, 1983). Alternatively, a psychological viewpoint sees CS as a potentially conscious plan an individual employs to solve a problem in order to reduce or replace some element of meaning or form in an initial communicative goal (Færch & Kasper, 1983a). That is to say, there have been two primary features of CS use—conscious and problem-oriented. However, Cook (1993, p. 119) provides a definition that is more directly linked to L2 learners when he says “a communication strategy is resorted to when the L2 learner has difficulty with communicating rather than when things are going smoothly—a spare tyre of emergencies.” Thus far, we may say that CSs are conscious attempts to overcome communication gaps and allow a strategic user of L2 to handle problematic situations when confronted with linguistic incapability.

The strategic processes involve several cognitive steps in a traditional face-to-face situation whereby L2/FL learners employ compensatory strategies to cope with a variety of communicative events. They enable them to accomplish their desired communicative goals in spite of insufficient linguistic capabilities. In one instance, a new word triggers a collaborative dialogue in which dyads of participants attempt to solve the linguistic problem through verbal or non-verbal means and body language to express the meaning of the word (Dobao, 2012). By asking for help from an interlocutor or by using appropriate strategies,

they are able to compensate for their linguistic deficiency and achieve efficient communication during a conversation or while reading an L2 text. What this type of problem-solving and conscious strategy use implies is that compensatory strategies are often used to improve an L2 learner's strategic competence and to help them make gains in communicative competence (Chen, 1990; Haastrup & Phillipson, 1983).

COLLABORATIVE LEARNING IN SECOND LANGUAGE ACQUISITION

Learning any given knowledge or skills is viewed as a socially embedded activity in which students collaborate with others to solve problems in order to complete tasks given by their teachers. In language learning, collaborative learning is strongly emphasized; after all, individuals possess different language skills which allow them to learn from one another. Supported by the underpinning theory of socio-culture, the zone of proximal development (Vygotsky, 1978) in particular assumes that social collaboration rather than individual learning facilitates cognitive development whereby more competent students give feedback on the language use of the less competent students which will in turn help the latter reflect on what language works or not. As in previous studies investigating the interaction between native speakers of the target language and non-native speakers, and between different proficiency levels of learners, their results suggest that negotiation of meaning provides language learners with profound opportunities to acquire form because it allows the lower proficiency learners to pay attention to incorrect output or the higher proficiency learners/experts initiate repair moves through clarifying the meaning of new vocabulary, for example.

Like examples from some research studies comparing learning performances between individual and collaborative output in phrasal verbs (e.g., "break into"), Nassaji and Tian (2010) found that learners who worked collaboratively produced more accurate phrasal verbs than those who worked individually when performing tasks.

In Dobao's (2012) study examining negotiated instances between native speakers and learners and between learners and learners, although the former interaction permitted learners to have more effective linguistic input and more meaning-orientedness rather than form correction, the latter was found to have higher levels of engagement during task performance.

CMC/SCMC FOR L2/FL INCIDENTAL LEARNING

A broad range of CMC tools adopted by language learners communicating with others in the target language provides an emerging opportunity for incidental learning through negotiation. Among these, text-based interaction promotes form acquisition for it allows learners to process the written form of messages with extra time when compared to that of an F2F environment. Such a line of research often observes the occurrences of form negotiation between NS-NNS and/or NNS-NNS interactions, and the frequency of language related episodes (LREs) between different types of tasks, or frequency of modified interaction between F2F and SCMC environments.

Studies, such as that of Eslami and Kung (2016) investigating successfully resolved instances in both interactions between NS-NNS and NNS-NNS—though the former produced more LREs than did the latter—reveal that incidental focus-on-form occurred in both interactions in a synchronous text-based environment. Particularly, knowledge co-construction is more likely to occur in NNS-NNS than in NS-NNS; that is, the more capable peers in NNS-NNS interaction who acted as linguistic resources provided words to their less capable counterparts who were lacking vocabulary words to convey meaning in the target language. It is the case that language learners are often found struggling to use lexical/linguistic items appropriately or to elaborate on the items in a communication situation. In Darhower's (2008, p. 58) study, when a learner used an inadequate word "incapacity [guys]"/"special guys" to describe people who are physically handicapped, her interlocutor, a native speaker, initiated a series of repair moves to ensure that the intended meaning was conveyed by the learner, e.g., clarifying and confirming the negotiated item "handicap" or expression "people with disabilities" instead of the original form "incapacity." In so doing, the negotiated cycle enables the learner to produce the newly learned item in the subsequent turn and helps her to acquire the correct form.

AN EMPIRICAL STUDY ON TEXT-BASED NEGOTIATED INTERACTION OF NNS-NNS AND NNS-NS ON FACEBOOK (LIU, 2017)

In order to address incidental vocabulary learning through negotiation, the empirical study conducted by the author of this article examined negotiation instances and interactional strategies during text chat on Facebook despite the research not dealing directly with vocabulary learning. In response to the inquiry of the incidental vocabulary learning, some of excerpts taken from that research will be reanalyzed here. The methodology and findings of the research discussed in the following paragraphs will provide a better understanding of how incidental form-focused interaction takes place in an SCMC environment.

METHODS

Participants

This research involved EFL learners and native speakers of English to form two types of interaction, NNS-NNS and NNS-NS. In the former, there were 5 pairs of higher and higher proficiency learners (H-H), and 5 pairs of lower and lower proficiency learners (L-L), whereas the latter consisted of 5 pairs of higher proficiency learners and NSs (L-N) and 5 pairs of lower proficiency learners and NSs (L-N), for a total of 40 participants (M = 10, F = 30). The lower proficiency learners were recruited from various disciplines (e.g., law, tourism, and business) in the university where the researcher taught, while the more capable ones came from the Applied English Department in the same university; native speakers came mainly from United States, United Kingdom, and New Zealand and resided in Taiwan while learning Chinese or teaching English when the research was conducted.

Tasks and Instruments

Two sets of postreading questions were based on students' textbooks. In the higher proficiency group, the reading passages with two topics of travelling and advertisements, were drawn from Mol (2008); there were four questions for each topic, such as "What does the short article talk about?" and "Where is the text likely to be seen?" In contrast, in the lower proficiency group, the texts regarding the topics of personality and online shopping were from Wilson (2011).

Facebook Text Chat

Facebook is acknowledged as one of the educational networking sites and one of the most popular social websites with a number of tools, such as online games and video/text chat, that enables users to manage privacy settings (to choose who can or cannot view their profiles) (Hew, 2011), encourages learners to interact with native speakers of the language (Kabilan, Ahmad, & Abidin, 2010) and engages students in professional topics (e.g., medical and clinical practices). Of the many Facebook tools available for pedagogical purposes, text chat, in terms of language learning, may develop learners' metalinguistic knowledge which may potentially lead to interlanguage (O'Rourke, 2005), by noticing the differences between the form used by themselves and by others during the negotiation of meaning and thereby may potentially activate strategic tactics to cope with insufficient knowledge. It may be reasonably assumed that compared to the asynchronous text chat, synchronous text chat may result in more modified exchanges between the participants when communication breakdowns arise during the course of task performances.

The research employed text chat to collect data that permitted the researcher to compare the results among the dyads. Each dyad was set up in a chatroom on Facebook. The participants worked with their partners and at the same time they were also informed to use text chat. In order to collect chat logs, each chatroom was created by the researcher who invited dyadic participants to join; despite the researcher being present in each chatroom, she by no means interacted with any participant during task performances.

Language-Related Episodes (LREs) and Data Analysis

A language-related episode (LRE) refers to any segment of language use by a learner producing incorrect linguistic items or solving language-related problems during face-to-face interaction (Swain & Lapkin, 1995). LREs are coded in chat scripts and counted in terms of frequency and turns. Turns concerning interactional strategy use for resolving linguistic problems encountered by an interlocutor were analyzed in the study. A turn refers to "each time there was a transfer of the 'floor' from one participant to the other" (Smith, 2003). However, a turn produced in an SCMC environment contains one or a few lines of messages conveyed by an interlocutor. Frequencies of the strategy use were tallied. The adopted modified interaction model in Figure 1 provided by Varonis and Gass (1985) illustrates two parts of nonunderstandings, trigger (T) and resolution; the former (T) is a word or sentence in the preceding turn of a speaker which is not understood by the hearer, while the latter consists

of an indicator (I), a response (R), and a reaction to response (RR). An excerpt below is to demonstrate how this model is applied in a communicative event when nonunderstanding arose in the text chat environment.

Figure 1. Model of non-understandings.

In excerpt 1, Jane, as a native speaker, and Ping, a learner, initiated a modified interaction when the learner did not know what the word “palm” meant during an information gap activity. Apparently, the word “palm”, as used by Jane, triggered the instance in turn 5; then, Ping explicitly initiated a request for clarification though he spelt it wrong as “paim” in turn 6. During the next turn, Jan responded to the request by explaining what it looked like; note that she immediately provided a correct form (grow) once she found she had mistyped a word (“grw”). Finally, the learner’s reaction to the response (the explanation of the word) implicitly acknowledged that she understood the word’s meaning since she directly responded to Jane’s question in Jane5 which related to task rather than to the explanation of the word.

[Excerpt 1—An exchange between NS and LA]

Jane5 Same, do you have two palm trees as well?

Ping6 What is paim [palm] tree

coconut

?

Jane7 Yes, they are the trees that coconuts grw on.

*grow

Ping8 I have three.

RR

It is worth mentioning that the patterns in excerpt 1 can be identified as collaborators and expert-novice dyads; the former characteristics are that dyad participants are engaged with each other’s ideas (Watanabe & Swain, 2007), both interactants contribute equal turns to text chat communication, and help his/her partner to elaborate on thoughts or to extend turns, whereas in the latter an expert scaffolds his/her less capable learner to learn new vocabulary or provides help to the learner (Watanabe & Swain, 2007). Note that the detailed analyses of the dyad patterns are presented in Liu (2017).

In Appendix A, five types of interactional strategy use included comprehension and confirmation checks, clarification requests, continuers, and asking for assistance. For instance, a comprehension check refers to a situation in which an interlocutor considers a word or phrase that might trouble his/her partner’s understanding and ensure whether s/he understands it. In Appendix A, an example illustrates that Joyce asked her partner whether he knew the word “stubborn.” A clarification request often means that a learner’s turn with an error triggers a repair move to clarify the meaning of the form because a nonunderstanding has arisen during a conversation. Clarification requests are often in interrogative utterances such as “What do you mean?” and “Can you please elaborate on this?” A continuer strategy indicates that one interlocutor signals the other to continue what has to be done.

Procedure

Liu's (2017) research was conducted in a synchronous text-based environment by observing how the dyadic pairs interacted in real time by typing messages to complete given tasks. Prior to the study, the researcher briefly described her research plan to her potential students in her classes such as advanced listening and speaking in English and general English courses. She then distributed the call-for-participants (CFP) flyers to the students, which stated what they were expected to do, e.g., how much they were paid and how long the research would last. More importantly, issues concerning research ethics, such as protecting their privacy, were addressed in the flyers. Similarly, the researcher approached native English speakers who were informed about the ethical issues as stated in the CFP flyers.

Each task taking place in Facebook chat rooms was completed by the dyads each week; all the participants were told that they would have to complete a task within one hour, that each pair could arrange their chat at their convenience, and that they should work together at the same time. For lower proficiency learners, they were not allowed to use a dictionary for new words as this would encourage them to employ interactional strategies.

RESULTS

The results first suggest that all dyads tended not to correct linguistic errors since 104 errors (out of 426) were found corrected while 322 errors were left uncorrected. Specifically, interaction between H-H dyads yielded more repair moves than the other three types of dyads. Due to capability in the target language, H-H dyads had more successfully resolved instances than L-L dyads. Moreover, the H-H dyads employed more interactional strategies than the other three types of dyads. According to the assumption of Liu (2017), compared to other dyads, H-H dyads were more likely to focus on form and meaning which resulted in more negotiation instances. Equally important is that the text chat allowed the H-H dyads to have more opportunity to look back at the contents of text chat.

To emphasize the incidental form-focus interaction, two excerpts taken from Liu (2017) will be reanalyzed. The following exchange between two high proficiency learners, Ken and John discussed one of postreading questions. A lexical item "challengeable", coined by Ken, triggered the modified interaction; despite the fact that the coined word did not hamper John's understanding, he provided the correct form "challenging" to Ken by using a confirmation check. In this case, there is an important bearing: although the two learners had encountered less communication difficulty in expressing their ideas, to some extent they still had some kind of linguistic gaps. In Ken's case, Ken might assume that most adjective items contained the suffix "able" rather than a gerund form "a verb + ing". John corrected the form and politely made a comment about the error (in John31 turn). Ken in turn responded to John's feedback by retyping the correct form (in Ken30 turn), illustrating that the feedback move drew Ken's attention to the correctness, and he in turn used the correct form in the next turn, thus making the negotiated item learnable.

Ken28: Well, living alone is quite challengeable.

John29: Do you mean challenging?

- Ken30: Sorry for my mistake—challenging not challengeable.
 John31: Haha, challengeable is not a word.
 Ken32: ☺

As noticed, the following exchange is mostly meaning-focused since Sam (a native speaker) neither corrected Jane's lexical errors (e.g., "save") and misspellings (e.g., "grounp"), nor pointed out those errors. Instead, he (in Sam19 turn) helped her to produce output by clarifying the unclear message in Jane18 turn which did not respond to his question in the previous turn. In Jane18 turn, there were numerous grammatical/lexical errors and semantic inappropriateness. Instead of explicitly correcting errors, Sam expressed his opinion about his preference (in Sam22) with a feedback move "... I need to consider..." on Jane's erroneous output "... I don't need considered..."

- Sam15: Do you think they have more freedom?
 Jane16: Yes, I think they are.
 Sam17: In your opinion, do you prefer travelling as a backpacker or with a tour group? Why?
 Jane18: It just not save for a alone girl travel as a backpacker. If I can gather some partner together, I would like as a backpacker.
 Sam19: Why?
 Sam20: What do you think are the advantages over a tour group?
 Jane21: The advantages over tour group, those are: I don't need considered the accommodation, like food, hotel, transportation....
 Sam22: I always prefer to travel without a tour group because then I can stay longer at a place I like. If I'm with a group I need to consider the other people.
 Jane23: But, I want to be "flashpacking".

CONCLUSION

This review article has mainly focused on the effect of incidental learning on vocabulary gains through negotiation in SCMC since to obtain vocabulary knowledge requires learners to use the newly acquired vocabulary in different contexts. Through negotiation for meaning, learners are able to pay attention to incorrect lexical items or inappropriate word usages that trigger communication difficulty in the language. Hence, there are several pedagogical implications. First, learners are encouraged to learn new vocabulary through interacting with others; by doing this, they will be able to notice their errors and to attend to the correct forms. Second, CMC technologies provide learners with ample opportunity to learn vocabulary incidentally. Using CMC allows learners to communicate with others from the target cultures or without time and space constraints. There are many benefits to using CMC technologies, especially for text chat; for example, when learners do not understand lexical items, they are allowed to scroll up and down on the screen and this may help them reduce anxiety or nervousness. Also, compared to an FTF environment, correct and incorrect forms that appear on the screen may become more noticeable. Finally, it may be useful to instruct language learners to acquire interactional strategies within the classroom in order to help them to use

the learned strategies in different situations and, more importantly, to facilitate more effective incidental learning.

APPENDIX A - INTERACTIONAL STRATEGY USE

Strategies	Excerpts (strategy use is underlined in excerpts)
Comprehension checks (Long, 1983; Bower & Kawaguchi, 2011)	1. Joyce13: two sisters have different personalities, <i>do you know stubborn?</i> Liam14: yes Note: a comprehension check is used to check whether a conversational interlocutor understands what has been said. Excerpt 1 taken from an L-L dyad indicates that Joyce checked on Liam's understanding of the word "stubborn".)
Confirmation checks (Long, 1983; Foster & Ohta, 2005)	2. Mary20: and is broken about using 3 months Kate21: <i>are you sure it has been used for 3 months?</i> Note: a confirmation check refers to an expression given by an NS to ascertain whether a preceding utterance has been understood or heard by his/her interlocutor during conversation. Excerpt 2 demonstrates that Mary as a learner misinterpreted the reading text, so Kate as an NS raised the question to confirm whether her understanding of that part of the text was correct.
Clarification requests (Lyster, 1998; Bower & Kawaguchi, 2011)	3. Lin32: ship is send? Jack33: <i>Sorry I don't understand. What do you mean "ship is send?"</i> Note: a clarification request as corrective feedback refers to the utterances produced by learners which contain errors and so need to be corrected (Egi, 2010; Jepson, 2005). Excerpt 3 shows that the native speaker Jack did not understand what the learner Lin had said as the learner attempted to ask whether "ship" here meant "send".
Continuers (Foster & Ohta, 2005)	4. Emily19: <i>Number two</i>, I think she spend too much money at shopping online Lisa20: I know. Note: a continuer is defined as "an utterance that shows that the talk is unproblematic prompting the speaker to go on." In this current study continuers were used when an individual wanted to continue reading another question from a text. In Excerpt 4, when the learners Emily and Lisa, an H-H dyad, had completed the first reading comprehension question, Emily invited Lisa to work on the second comprehension question.
Asking for assistance	5. June16: I don't know how to answer the question, <i>can u help me</i> Lily17: sure, what difficulties are you having? Note: a short exchange between June and Lily, one of H-N dyads, demonstrates the strategy deployment in Excerpt 5 where the learner asked help from her expert interlocutor (June 16) in order to complete the task.

Chapter 23

EFFECTIVENESS OF VOICE THERAPY IN VOCAL FOLD NODULES

Victor Valadez* and Rosa Isela Magallanes

Instituto Nacional de Rehabilitación, Mexico City, Mexico

ABSTRACT

Vocal fold nodules are a functional voice disorder associated with voice misuse and abuse. They are benign masses, typically located on the membranous aspect of the vocal fold. Voice therapy is a process that aims to bring voice to a level of fitness that can supply occupational, emotional and social needs, knowing that not all patients will achieve a normal voice. Voice training usually consists of a combination of “direct” and “indirect” treatment techniques. Direct techniques focus on the underlying physiological changes needed to improve an individual’s technique in using the vocal system. These techniques are aimed to modify and/or improve vocal fold closure (adduction), respiratory patterns, resonance, pitch and articulatory tension. In contrast, indirect procedures concentrate on contributory and maintenance aspects of the voice disorder and may involve relaxation strategies, counselling and explanation of the normal anatomy and physiology of the vocal tract, explanation of the casual factors of voice disorders and voice care and conservation.

Keywords: vocal folds, vocal cords, vocal nodules, voice, rehabilitation, therapy

INTRODUCTION

Vocal fold nodules are a functional voice disorder associated with voice misuse and abuse. They are benign masses, typically located on the membranous aspect of the vocal folds. Common symptoms include hoarseness, breathiness, vocal fatigue, straining, rough voice and vocal range decline. [1, 2]

* Corresponding Author Email: vvaladez@inr.gob.mx; vicman71@hotmail.com.

Vocal nodules are a frequently occurring type of voice disorder. Their incidence appears to be related with occupation. [3]

Voice therapy can be conceptualized as a process aiming to bring voice to a level of fitness which can be considered achievable by the patient. This level of improvement should be enough to supply the patient's emotional, social and occupational needs. It should be pointed out that not all patients can achieve an entirely normal voice. [4]

Voice therapy usually starts from awareness of the voice disorder. However, when children exhibit voice disorders, it is quite difficult for them to be aware of their voice abnormal voice quality or their vocal symptoms. [5, 6] Thus, in these cases working with the family becomes essential.

Several authors have reported that vocal treatment of dysphonia, whether organic or functional, can address several aspects which may be applicable to most cases. These include relaxation exercises, breathing exercises and voice projection and impost. [4]

Holmberg, et al. [3] reports that clinicians use a variety of therapy approaches to treat vocal nodules. A main goal of the treatment techniques is to reduce muscle tension and hyperfunction and optimize vocal behavior to reduce the trauma to the vocal folds, so that aerodynamic forces and acoustic properties approach normal values. The realm of the therapy can be divided into four basic approaches: 1. vocal hygiene; 2. direct facilitation; 3. Relaxation; and 4. respiration. In addition, it is generally agreed that some time should be devoted to "carryover" newly learned vocal behaviors to "real life" situations outside the therapy setting. Perceptual judgments have long been the major clinical tool for voice evaluation. The clients seek treatment in part because their voice does not sound normal. Speech clinicians use both formal and informal perceptual judgments in each session with the client, and perceptual judgments always serve as a complement to visual inspection of the larynx and vocal folds. In addition, perceptual parameters are used as standards against which objective measures of voice are evaluated. It has been a problem that large intra - listener and inter - listener variations have been found in perceptual evaluations, which therefore have been criticized as being too subjective to have real clinical value. In contrast, good agreements among listeners have been shown in other studies. Much of the recent research reports have focused on objective measurements of vocal function. Unfortunately, the techniques for obtaining such signals are not always easily accessible in clinical centers. Moreover, analyses and interpretations of the results are not straightforward. Identifying voice quality parameters that reflect underlying vocal function should have strong clinical value.

An important goal is to develop reliable methods for perceptual evaluations of voice quality, and to establish reliable relationships between perceptual judgments and objective measures of underlying physiological conditions.

Endoscopic findings have demonstrated vocal hyperfunction in patients with vocal nodules undergoing behaviorally based voice therapy. [3] Based on these findings, it has been possible to define relationships between therapy approaches and desired modifications in vocal function which can be assessed and detected by selected voice quality parameters, hence contributing to the development of perceptual criteria for evaluating treatment outcomes in cases of vocal nodules. At the onset of voice intervention, no differences have been found between evaluations of patients' recordings that have been repeatedly examined for reliability. However, after the intervention period, it has been demonstrated that nodules decreased in size either bilaterally or unilaterally. Also, it has been reported that the

surrounding edema that can be found at the onset of voice intervention either unilaterally or bilaterally is significantly decreased after intervention.

In a previous report [3] mean values were always high ($\alpha > 0.80$) for the parameters: press, breathiness, lack of sonority, scrape, and dysphonia, while mean α for other parameters varied across assessments. Strong ($r > 0.70$) positive correlations were found in several assessments between press and gratings; roughness and scrape; and between breathiness and aphonic instances, including lack of sonority and instability. Vocal fry was not strongly correlated with any of the other parameters, but a few cases of significant negative correlations were found between vocal fry and breathiness and aphonic instances. Overall dysphonia before and after therapy was strongly correlated with press, breathiness, and scrape. No cases of significant correlations were found between press and breathiness. Endoscopic ratings of vocal status showed that none of the vocal nodules had completely disappeared after completion of the therapy. This finding is in agreement with histologic studies that suggest that more permanent types of tissue damage may be associated with the formation of nodules, e.g., fibroblastic response involving increased fibronectin decomposition. Thus, the positive impact of therapy is not necessarily associated with a complete amelioration of the nodular lesions. However, the fact that the nodules had decreased in size after therapy for most patients, as well as findings of reduce edema, strongly suggest that voice therapy has a trauma-reducing effect for the majority of patients. Hyperfunctional vocal behavior appears to have decreased. Thus, there seemed to be a good potential that the compensatory “vicious circle” of further increased muscle tension and increased subglottal pressure leading to escalating trauma could be stopped by voice therapy. The combined results from endoscopic and perceptual evaluations suggest that alterations in vocal status and voice function were reflected in parameters of voice quality. These results of decreased nodules and improved voice quality suggest that the voice therapy had a positive effect for a majority of the patients with vocal nodules.

A Cochrane’s systematic review [7] reports that that voice training usually consists of a combination of “direct” and “indirect” treatment techniques. Direct techniques focus on the underlying physiological changes needed to improve an individual’s technique for using the vocal system. These techniques are aimed to modify several functions or behaviors including: vocal fold closure (adduction); respiratory patterns; resonance; pitch; and articulatory tension. In practice this means to guide intensive training concerning modifications of correct posture, breathing techniques and the production of various sounds like humming, singing musical scales or yawing. Indirect techniques, on the other hand, concentrate on contributory and maintenance aspects of the voice disorder and may involve relaxation strategies; counseling; explanation of the normal anatomy and physiology of the vocal tract; explanation of the casual factors of voice disorders; and voice care and conservation. The systematic review did not found sufficient evidence to support statements that either direct or indirect or even both combined are actually effective for improving vocal functioning when measured using self-reported outcomes and when compared to no intervention. [7]

Some reports have evaluated the effectiveness of training using direct intervention techniques alone compared to no intervention. In general, direct techniques focus on the underlying physiological changes needed to improve an individual’s technique in using the vocal system. These techniques include training focused on posture, respiration, release of tension in the vocal tract, resonance and voice projection. [7]

Voice training can consist of vocal warm-up and cool-down as well as group activities regarding the psychodynamics of voice production. In order to promote vocal warm-up, facilitating sounds, body movement techniques with sounds production, overarticulation exercises, semi-occluded vocal tract exercises and chant talk exercises have been used. Direct voice training can also include warm-up, stretching, contracting, forced adduction and strengthening exercises to be practiced at home, twice per day, preferably morning and evening for a six-week period. [7].

Indirect voice training alone has been compared to no intervention. Indirect techniques concentrate on the contributory and maintenance aspects of the voice disorders (such as lack of knowledge). Indirect training can consist of providing information on the mechanics of voice production, the amount and type of voice use, vocal behaviors thought to be traumatic for the vocal cords, hydration issues, and lifestyle and diet factors that can support or interfere with a healthy voice. Patients are informed of the prevalence and impact of voice problems in teachers; basic anatomy and physiology of voice production; symptoms of voice disorders; strategies to reduce harmful vocal behaviors; managing and minimizing health factors for the development and maintenance of voice problems; and changes in the speaking environment than increase vocal efficiency and reduce vocal injuries. [7]

Lectures can be offered concerning the main factors causing vocal loading in teachers, methods available include: avoid overloading and basics of economic versus non-economic voice use. The voice training is geared towards gaining ease and endurance in voice production as well as getting rid of any poor vocal habits. The learning methods are usually introspections, discussions, voice exercises and individualized homework aimed to finding economic voice production, i.e., avoidance of excessive muscle tension of the larynx; deep breathing technique; firmness of phonation without effort; well-resonating voice quality to improve audibility; and adequate individual pitch and loudness range and variation. Patients can also receive voice hygiene lectures and in addition undergo voice massage TM in several sessions. Voice Massage TM consists of manipulation of voice and speech production muscles of the larynx, respiration and articulation. It also includes some vocal and respiratory exercises during manipulation. [7].

Some studies focus on direct and indirect voice training combined. Interventions consist of lectures and a practical session. The lectures concern anatomy and physiology of phonation, causes and predisposing factors to abnormal vocal fold pathology, warning symptoms of vocal fatigue, voice ergonomics (i.e., vocal hygiene, strategies to reduce vocal demand in the classroom, and changing behaviors in daily life to reduce vocal abuse), classroom acoustics, and amplification systems. Practical sessions consist of group voice therapy training: efficient respiratory behavior; laryngeal muscle relaxation; manual circumlaryngeal therapy; relaxed voicing with elimination of hard glottal attack, chewing, voicing, yawn-sigh, chant talk and pitch inflections; proper oral-nasal resonance; and developing greater oral opening [7].

Another study evaluated the effectiveness of two different programs of voice treatments on a heterogeneous group of dysphonic speakers and the stability of therapeutic progress during long term follow-up post - intervention period by using a limited multidimensional protocol of evaluation. Pathologies included vocal nodules, polyps, angiomatous polyps, Reinke's edema and hypotonic dysphonia. Patients were assigned to one of two groups, the participants in the first group received voice-therapy consisting of five phases of basic information and counseling, relaxation, breathing, emission and placement, and carryover.

The total number of sessions per participant was 24 which were conducted over a period of 12 weeks. Each session lasted approximately 45 minutes. In contrast, participants included in the second group received a voice hygiene program. These patients followed guidelines for a program previously described as successful when it was used for teachers. An initial informative session lasting approximately 60 minutes was provided. The results of this study suggest that voice-therapy (direct approach) seems to be more effective than the vocal-hygiene program (indirect approach). The significantly better improvement was detected in most of the hard - dimensional variables which were used for assessing outcome, including: Aerodynamic measurements, acoustic parameters and self – rating.

Qualitative – perceptual variables including: laryngoscopy findings and spectrographic analysis also showed better outcome in patients undergoing the direct approach. The stability of these changes is usually extended during long term post - intervention follow-up period. [8]

According to another systematic revision, direct voice therapies seem to be more effective than indirect voice therapies. [9]

In studies of some specific voice therapies methods, such as manual laryngeal tension reduction and the Accent method, positive post - therapy outcomes are more frequently reported than in other studies in which therapy methodology is not clearly defined. [10]

Voice therapy approaches are often divided into three main categories: hygienic (improving behaviors than can lead to injury of the vocal folds), symptomatic (targeting treatment of abnormal voice quality in the resulting phonated voice), and physiological (optimizing voice production). These techniques have proven to be effective both in adults and in children. However, it should be pointed out that in children, the compliance of the family for modifying family's style of voice use is essential for a successful outcome. [10, 11]

CONCLUSION

Vocal nodules are the pathological result of vocal abuse and misuse. This pathology has been found predominantly in voice professionals and patients with an inadequate vocal hygiene including children. The resulting dysphonia brings consequences in psychological, socio-economic, family, and labor aspects. The best approach for tackling this disorder seems to be a multidisciplinary methodology, covering both medical and therapeutic aspects, using several therapeutic techniques including indirect and direct approaches.

An early diagnosis and treatment can prevent surgical treatment as well as consequences involving professional and personal aspects of the patient's life style.

Chapter 24

SPEECH AND LANGUAGE PATHOLOGY INTERVENTIONS IN CRITICAL CARE: A RETROSPECTIVE VIEW

Kathleen V. Roeder*

Department of Speech and Language Pathology,
Beaumont Health System, Royal Oak, MI, US

ABSTRACT

Speech and Language Pathology interventions in critical care purport to improve patient care and patient outcomes by addressing the risk for aspiration due to iatrogenic dysphagia related to tracheostomy tube placement, ventilator dependency and critical illness myopathy. Many Speech Pathology recommendations address NPO status, need for alternative feeding via Corpak tube and need for PEG tube placement. A retrospective analysis of 20 patients admitted to the various medical neurosurgical and surgical ICU's analyzed patients from two groups: those who were kept NPO until a Speech and Language Pathologist assessed swallow function and those who had an oral diet assigned by the medical team without an initial formal Speech Pathology swallow assessment. Among the parameters investigated were LOS in the ICU, need for re-intubation, number of NPO status days, recommendation for Corpak tube or PEG tube and discharge status with respect to oral feeding, tube feeding and modified diet.

Keywords: swallowing, dysphagia, tracheostomy, gastrostomy, speech and language pathology

INTRODUCTION

Speech and language Pathology interventions in critical care purport to improve patient care and overall patient outcomes by addressing the risk for aspiration due to iatrogenic dysphagia from tracheostomy tube placement, vent dependency and critical illness myopathy.

* Corresponding Author Email: roederkathy@gmail.com.

[1] Many Speech Pathologists directly recommend NPO status, post suggestions for placement of a Corpak tube due to NPO status and suggest PEG tube placement. [2] Specific recommendations for oral feeding with modified diets are part of the Speech Pathology plan of care. At the conclusion of their evaluations Speech Pathologists generally decide that patients have benefitted from these recommendations. However, the medical team may conclude that patients seen by Speech Pathology receive higher numbers of recommendations for tube feedings, have longer patient stays and that the recommendations by Speech Pathology further complicate the medical course; the placement of feeding tubes can cause more complications, result in dislodged tubes and extra procedures for replacing them, complicate the discharge plan and therefore increase length of stay. [3]

PURPOSE

The purpose of this study was to compare the clinical outcome for ICU patients who were kept NPO until a swallow assessment was completed by Speech Pathology with patients who were initially given oral diets by the medical team in the absence of a formal Speech Pathology assessment.

MATERIALS AND METHODS

A retrospective analysis of 20 patients placed in the ICU between January 1, 2014 and February 28, 2014 was completed. The data collected addressed the patients' overall length of stay, the total number of procedures completed by Speech Pathology; the number of NPO days recommended by Speech Pathology; the number of instances in which feeding tubes were recommended by Speech Pathology; the number of patients requiring re-intubation for respiratory distress, and the discharge plan specific to oral feeding recommendations.

Patients were divided into two groups. In Group 1, 10 of the patients reviewed had been NPO until seen by a Speech Pathologist. Of this first group, the medical team had determined that the patient would be best served by remaining NPO until a formal clinical swallowing assessment could be completed. This assessment took place bedside with the actual number and type of food items presented left to the discretion of the evaluating clinician. The recommendation for an instrumental evaluation, specifically Modified Barium Swallow Study, was made by the Speech Pathologist who completed that initial clinical swallow assessment and not by another member of the medical team.

In Group 2, 10 of the patients reviewed were placed on oral feeding by the medical team and were not initially seen for a standard clinical assessment by Speech and Language Pathology. Either the rounding physician or the bedside nurse determined that the patient had a functional swallow for oral feeding. This last group of patients was eventually assessed by Speech Pathology, either for later issues potentially related to dysphagia, or for interventions related to parameters outside of swallow function, specifically dysphonia or language and cognitive dysfunction.

The patients selected retrospectively were randomly chosen from those placed in the various surgical, neurosurgical, cardiac and medical ICU's during the two month period noted

above. Patient diagnoses were highly variable and included multiple trauma with traumatic brain injury, subarachnoid hemorrhage, complications associated with cardiovascular surgery, hemorrhagic CVA, craniotomy for brain tumor excision, and post-surgical respiratory failure. All of the patients had been intubated, some of them had tracheostomy tubes at the time of evaluation; other patients were tracheostomy tube free.

RESULTS

Results of Patients with NPO Status Until Seen by Speech and Language Pathology

The Average Number of ICU Days:	9.5.
The Average Number of Visits by Speech Pathology:	3.3
The Number of Patients Receiving Modified Barium Swallow Study:	3
Average Number of NPO Days After Seen By Speech Pathology:	2
Number of PEG Tube Recommendations:	0
Number of Corpak Tube Recommendations:	1
Number of Modified Diets Recommended:	7
Number of Patients Discharged on Soft or Regular Diet with Thin Liquid:	7
Number of Patients Discharged from the Hospital on Thickened Liquids:	2.
Number of Patients Discharged to a Long Term Care Facility with Corpak Tube in Place:	1
Number of Re-Intubations Specific to Presumed Oropharyngeal Aspiration:	0

Results of Patients Starting Oral Feeding before Evaluation by Speech and Language Pathology

The Average Number of ICU Days:	11.1
The Average Number of Visits by Speech Pathology:	4
The Number of Patients Receiving Modified Barium Swallow Study:	4
Average Number of NPO days after being seen by Speech Pathology:	4
Number of PEG Tube Placement Recommendations by Speech Pathology:	0
Number of Corpak Tube Recommendations:	3
Number of Modified Diets Recommended:	9
Number of Patients Discharged on Soft or Regular Diet with Thin Liquid:	6
Number of Patients Discharged to ECF with PEG Tube in Place:	1
Number of Patients Discharged to ECF with Corpak tube in Place:	0
Number of Re-intubations Specific to Presumed Oropharyngeal Aspiration:	2

DISCUSSION

The ten patients In Group 1, who were NPO until seen by Speech Pathology for a formal clinical swallow assessment, had no instances of oropharyngeal aspiration. Two out of the second group of 10 patients developed increased respiratory distress and required re-intubation. While it is difficult to draw a direct correlation between increased respiratory distress and oropharyngeal aspiration, the medical team deemed aspiration a consideration to be resolved by a Speech Pathology evaluation. [4] On completion of a Modified Barium Swallow, both of these patients were found to have aspiration of at least one food and one liquid consistency. Unresolved questions include the possibility that the overall medical course was more complicated and that dysphagia was therefore a later consequence of those complications. It is certainly possible that the need for repeated intubation and prolonged NPO status as a result of intubation contributed to the MBS findings and that prior to re-intubation swallow function had been better. Also under consideration is the possibility that those two patients had less stable respiratory status than the others and developed increased risk for aspiration simply due to the added labor of trying to coordinate respiration with swallow initiation. [5] However, with any of those considerations in mind, a formal clinical swallow evaluation might have concluded that those two patients would be best served by short term NPO status while respiratory function stabilized.

With the exception of one patient who was seen for a language assessment post hemorrhagic stroke all of the patients in Group 2 developed some complication related to respiratory function that increased the medical team's concern for underlying dysphagia and associated aspiration as a potential factor in the change in respiratory status. Of the 10 patients in Group 2 who eventually received a consultation for Speech Pathology all but one of them were found to have dysphagia requiring at least a modified diet. Were the modified diets warranted? Should the patients have had Modified Barium Swallow Studies? Were those studies simply added cost? Was respiratory distress going to occur whether or not Speech Pathology was involved? Were the changes in respiration really associated with swallow dysfunction or were those events specific to other medical issues? While it is not within the scope of this simple retrospective analysis to determine whether the presence of Speech Pathology would have reduced the risks for increasing respiratory distress or prevented the need for re-intubation, these are important questions for both Speech Pathologists and the primary medical team. [6] The relative cost versus the relative gain from a formal swallow assessment for the ICU patient who develops increased respiratory compromise is a quality and safety issue for the patient and the critical care team.

So, if we cannot yet answer the questions posed above, what conclusions can be drawn from the information provided?

CONCLUSION

The conclusions we can draw from this small sample of ICU patients over a two month period are these:

1. No PEG tubes were recommended by Speech Pathology in either group.
2. 10% of patients in Group 1 received a suggestion for Corpak tube placement while 30% of patients in Group 2 received a suggestion for Corpak tube placement.
3. 30% of patients in the first group had Modified Barium Swallows Studies while 40% of patients in the second group had Modified Barium Swallow Studies.
4. No patients in the first group developed respiratory distress complicating length of stay or requiring re-intubation.
5. 20% of patients in the second group developed respiratory distress with aspiration a consideration but undetermined as a final etiology.
6. The total number of procedures completed by Speech Pathology was three for Group 1, and four for Group 2.
7. Group 2 had an increased number of NPO days.
8. Respiratory distress is often multifactorial and may not result specifically from aspiration, but aspiration does surface as a potential etiology when respiratory distress develops during a hospitalization.
9. Once the issue of respiratory distress and re-intubation surfaced, more procedures and less reliance on clinical bedside swallow evaluation also surfaced.
10. There was increased reliance on use of MBSS once patients had attempted oral feeding and then developed respiratory distress.

IMPLICATIONS FOR SPEECH PATHOLOGY AND FOR THE CRITICAL CARE TEAM

The formal clinical swallow evaluation can be an effective, timely and cost effective strategy for the ICU patient. A Modified Barium Swallow Study is not always needed before starting an oral diet. The best course of action in the critically ill patient who is increasingly challenged by weak breath support might well be to instate NPO status or limit po intake to compensate for generalized weakness, poor endurance and associated weak breath support until respiratory function stabilizes. [7]

While daily intervention from Speech Pathology is not easily proved cost effective in the ICU, an initial clinical evaluation and a limited number of follow up visits can be cost effective by forwarding patient progress through safe oral feeding without incurring the significant cost associated with numerous procedures. While the double blind study is the gold standard for accurate determination of outcomes, most physicians are reluctant to withhold services from one patient while providing them to another patient. Therefore, an ongoing data collection might well be an important starting point for determining patient outcomes. Most importantly, this retrospective analysis will result in the collection of data in our department from the point forward in order to identify the relative cost and safety benefit to the ICU patient from our service, as well as to identify potential costs and complications associated with Speech Pathology recommendations.

SPEECH SOUND DISORDERS PROTOCOL GUIDE FOR SPEECH AND LANGUAGE PATHOLOGISTS

Marisa Lousada^{1,*} and Margarida Ramalho^{2,†}

¹School of Health Sciences (ESSUA), University of Aveiro, Aveiro and Center for Health Technology and Services Research (CINTESIS), Porto, Portugal

²School of Health Sciences, Polytechnic Institute of Setúbal (IPS), Setúbal, Portugal

ABSTRACT

Children with speech sound disorders (SSD) dominate the caseloads of many speech and language pathologists (SLPs) and form a heterogeneous group [1,2]. The clinical practice with children with SSD involves several methods and theoretical assumptions. Different procedures should be considered in the assessment of children with SSD, e.g., case history, single word test, stimulability, oral motor-speech, phonological analysis (linear and non-linear), phonological awareness, syllable/ word shapes, intelligibility [3]. Also, a large number of intervention approaches are available for children with SSD [4,5], for example, minimal opposition contrast therapy [6], traditional articulation therapy [7], core vocabulary [8], cycles approach [9], phonological awareness [10]. It has also been suggested that some intervention approaches are more effective for some SSD subgroups [11–14].

More recently SLPs are also encouraged to use the International Classification of Functioning, Disability and Health (ICF) [WHO 15], or the International Classification of Functioning, Disability and Health Children and Youth Version (ICF-CY) [WHO 16] in order to contemplate not only the speech disorders (body structures/ functions) but also its impact in person's activities and participation and the contextual factors (environmental and personal) that affect communication. As professional associations suggests [ASHA 17, RCSLT 18, CASLPA 19] ICF can help SLPs using a common terminology system by adaptation of many classifications that are already in use.

Since clinicians have limited time and access to analyze all of the relevant studies about assessment and intervention for children with SSD and incorporate ICF in their clinical practice, we intend with this chapter to guide them to implement best practice for

* Corresponding Author Email: marisalousada@ua.pt.

† Corresponding Author Email: amargaridamcramalho@gmail.com.

children with SSD in terms of clinical process (since case history to intervention outcomes) and include ICF terminology in all process. Specifically we will present the *SSD protocol guide for SLPs*.

Keywords: speech sound disorders, assessment, intervention, ICF

INTRODUCTION

Speech sound disorders (SSD) are the most common diagnosis made by speech and language pathologists (SLPs) working with preschool and school aged children [1,2]. Some children have a speech sound disorder that is secondary to conditions such as hearing impairment, cognitive impairment or cleft lip and/or palate but for the majority the cause is unknown [2]. In this chapter we will focus on SSD of unknown origin.

Research has showed that SSD form a heterogeneous group, thus several procedures should be used in the assessment and intervention with these children. This chapter will present a proposal for the *SSD protocol guide for SLPs*. This guide provides current information about the terminology, assessment, and intervention and the use of the International Classification of Functioning, Disability and Health (ICF) [WHO 15], and the International Classification of Functioning, Disability and Health Children and Youth Version (ICF-CY) [WHO 16] in these disorders.

SSD PROTOCOL GUIDE FOR SLPs

The International Classification of Functioning, Disability and Health (ICF) is one of the World Health Organization (WHO) frameworks. The previous classification (International Classification of Impairments, Disabilities and Handicaps (ICIDH), published in 1980 focused in the disease, but ICF changes this paradigm, into bio psychosocial paradigm giving much importance to individual health and functioning.

According to Reed et al. [20] the ICF classification allows the documentation of the impact of health conditions on human functioning from the biological, individual and societal perspectives. Thus, ICF classification is very useful for SLP, since communication disorders can implicate body structures and functions and has consequences in person's activities and participation.

Also, ICF integrate contextual factors (environmental and personal factors). In environmental factors it is important to consider many physical, social and attitudinal environment which people live and conduct their lives [WHO 16]. For example, the SLP himself (e355 health professionals) can be considered as a facilitator or a barrier. When SLP is a facilitator he or she helps child with SSD, improving functionality in child's most important contexts (e.g., family routines, kindergarten, school and other social events). ICF conceptualizes functioning and disability as a dynamic interaction between a person's health condition and their Contextual Factors [WHO 15] (see Figure 1).

Several of international professional associations recommend the use of ICF in SLPs clinical practice aiming clinical goals, professional interest and scientific research in communication disorders. ASHA [21] suggests that SLPs apply ICF in all intervention

domains, such as prevention, assessment, intervention and scientific study of communication and swallowing disorders. In the same way, CASLPA [19] encourages the development of outcome measures considering ICF and the ICF-CY classifications.

The Resource Manual for Commissioning and Planning Services for SLCN, published by Royal College of Speech and Language Therapists [22] describes the impact level that speech sound disorders can have in children's system, for each ICF dimensions. The impairment can involve sound production, phonological awareness, phonological processing, phonological template, segmentation skills, mental representation of words in the lexicon and prosody. In the same way, activity can be affected as well, in areas like intelligibility of speech, reading and writing skills. Once reduced, communication skills can affect self-esteem, self-identity, relationships, educational and work attainment [RCSLT, 22].

Figure 1. Representation of the *International Classification of Functioning, Disability and Health* (ICF) [WHO 15].

One of the principal aims is to provide an interdisciplinary consensual terminology for health professionals by using a standard language and framework. However, in SSD area there are some issues with the terminology used and the underlying problems for diagnosis description, which could have a considerable impact in assessment and intervention. These particular aspects are discussed in the following sections.

BODY FUNCTIONS

McCormack and Worrall [23] reported the ICF Body Functions related to speech-language pathology. The application of ICF codes to SSD usually contemplates primarily *articulation functions* (b320). Other codes are also referred (*mental functions of sequencing complex movements* – b176 and *fluency and rhythm of speech functions* – b 330) to describe SSD of unknown origin.

In some SSD sub-groups, where linguistic competence is affected (e.g., phonology), it's not common the use of language related codes in the assessment/analysis and intervention [23, 24].

In the authors' perspective, phonology is one of the linguistic domains, so *mental functions of language* (b167) should be used to classify some SSD sub-groups (phonological delay, consistent atypical phonological disorder, inconsistent phonological disorder and CAS/DVD) (see table 1).

Table 1. SSD sub-groups proposed by Dodd [25] and possible related ICF codes

Dodd's five subgroups	Codes usually used to classify SSD [24]	Proposal considering phonology as a linguistic process*
Articulation disorder	b320	b320
Phonological delay	b320	b167 b320
Consistent atypical phonological disorder	b320	b167 b320
Inconsistent phonological disorder	b320	b167 b320
Childhood apraxia of speech (CAS)/ Developmental verbal dyspraxia (DVD)	b320	b176 b320 b167

* Codes are hierarchy organised by level of impact.

ACTIVITY AND PARTICIPATION

The Activities and Participation component of the ICF describes the human functioning from the individual to a societal perspective. So the *activity* is referred to “the execution of a task or action by an individual” - individual perspective. *Participation* include “involvement in a life situation” - societal perspective [WHO, 16].

Regarding the third chapter of ICF, the *Activity and Participation component* focuses on *Communication* describing it in terms of type of message received or produced (*communicating - receiving* (d310-d329) and *communicating - producing* - d330-d349), whether it is non-verbal or verbal (modality) and in terms of the modality the person uses to communicate like body gestures and drawings. However, communication activity and participation is also mentioned in other chapters like *learning and applied knowledge* or *interpersonal interactions and relationships* [26].

CONTEXTUAL FACTORS

The second part of ICF is related to Contextual Factors that “represent the complete background of an individual's life and living” (WHO, 2001, p. 16) and contain two components - Environmental Factors and Personal Factors. Environmental Factors include all aspects of the external world of an individual's life that may have an impact on his or her

functioning. Personal Factors comprise “features of the individual that are not part of the health condition” such as gender, age, and coping styles (WHO, 2001, p. 17).

CLINICAL HISTORY

Case history questions allow SLPs to obtain background information about the child to a better understanding of the problem and to plan treatment. This section will focus on specific questions for SSD and its relation to ICF.

The aim of the questions about communication history is to determine if the child has evidenced delay in the attainment of principal language milestones [27]. Questions about birth and medical history are included to know if any medical factors could have influenced communication development, to conclude if the child has a SSD secondary to other condition (e.g., hearing impairment – b230 hearing functions) or an SSD of unknown origin.

When SLP do the child's clinical history, he or she should also consider environmental factors like *support and relationships* (e3), such as *immediate family* (e310) or *friends* (e320), or *attitudes* (e4) (e.g., *individual attitudes of immediately family members* (e410). Thus, social history will help to determine if a child has had opportunities to communicate and if the environment is sufficiently rich to foster adequate communication development [27]. It is also important to know for example if the caregivers are always correcting speech errors because too much correction can have a negative impact (e.g., frustration). It is essential to balance between correcting errors, praising success and letting some errors pass [28]. It is very important to know about the environmental factors and assess their impact on SSD and intervention process.

Finally, the aim in obtaining an education history is to know if a child has received school services (e.g., regular class at school (e585)) and also if he or she received any special services (special education and training services (e5853)) [27].

ASSESSMENT

Different procedures should be take into account in the assessment of children with SSD, specifically, case history, single word test, stimulability, oral motor-speech, phonological analysis (linear and non-linear), phonological awareness, syllable/ word shapes, intelligibility [3]. McLeod and Threats [24] presented a list of assessments and analysis of SSD children's and the ICF-CY codes usually associated: *auditory perception* (b1560), *fluency and rhythm of speech functions* (b330), *mental function of sequencing complex movements* (b176), *articulation function* (b320) (body functions); *structure of the mouth* (s320) (body structures); *learning to read* (d140), *communication* (d3), *interpersonal interactions and relationships* (d7), *major life areas* (d8), *community, social and civic life* (d9) (activity and participation).

Considering that SSD covers different underlying problems (e.g., motoric, phonological) in the present proposal other codes should be added to a better description of the assessment/analysis used. For example when the SLPs use a phonological analysis in a child with a phonological delay or disorder, the code *mental functions of language* (b167) seems to help in a better representation of the type of SSD, because in a phonological perspective

phonology is part of language. Mental functions of language refer to "specific mental functions of recognizing and using signs, symbols and other components of a language" (WHO, 2007, 58) and phonology is one of the language components. It is important to dissociate phonetics (articulation based problems) from phonology (linguistically-based problems) [29,30]. Thus, in a way to improve evidence-based practice, this underlying concept should be present in the assessment and intervention with children with phonologically based SSD.

INTERVENTION APPROACHES FOR CHILDREN WITH SSD

At the moment different intervention approaches are used for children with SSD [4,5], e.g., minimal opposition contrast therapy [6], traditional articulation therapy [7], core vocabulary [8], cycles approach [9], and phonological awareness [10].

Table 2. Comparison of the Impairment Scale proposed by Enderby et al (2006, p. 90) and ICF Body Functions and Structures extent or magnitude scale of an impairment (WHO, 2001) for phonologically based SSD

Enderby et al. (2006)	ICF
Impairment	Body Functions and Structures
0 Totally limited sound system; uses no recognisable consonants.	xxx.4 Complete impairment (total,...) 96-100%
1 Speech system restricted; uses a few recognisable sounds including some consonants.	xxx.3 Severe impairment (high, extreme,...) 50-95
2 Good use of consonants and vowels at single word level but poor transfer of sounds into sentences. May have 25% to 50% suppression of inappropriate processes.	xxx.2 Moderate impairment (medium, fair,...) 25-49 %
3 Capable of clear speech when thinking about it and prompted, but clarity deteriorates in spontaneous speech. May have 50% to 75% suppression of inappropriate processes.	
4 Persistent minor immaturities; may have typical processes at a later age or one atypical process.	xxx.1 Mild impairment (slight, low,...) 5-24 %
5 Age-appropriate speech	xxx. 0 No impairment (none, absent, negligible,...) 0-4 %
	xxx.8 not specified
	xxx.9 not applicable

Intervention studies indicated that some intervention approaches are more effective for some SSD subgroups, for example phonological therapy was found to be more effective than articulation therapy for children with phonologically based SSD [13,14]. Also, according to Dodd and colleagues [11,12] children with inconsistent phonological disorder received most

benefit from the core vocabulary approach and children with consistent speech disorder improved more with phonological contrast therapy.

Concerning outcome measures, studies typically provide speech severity indices, for example, percentage of occurrence of phonological processes and percentage of consonant correct (PCC) score [4]. However, intelligibility should also be used as an outcome measure as with this measure we can analyse the impact of the disorder in the activity and participation level (see Tables 2 and 3).

Table 3. Comparison Activity and Participation scales of ICF (WHO, 2001) and Enderby et al. (2006, p. 90) for phonologically based SSD

Enderby et al. (2006)		ICF
Activity	Participation	Activity and Participation
0 Completely unintelligible to familiar and non-familiar listeners.	0 Unable to fulfil any social/educational/family role. Not involved in decision-making/no autonomy/ no control over environment, no social integration.	xxx.4 Complete difficulty (total,...) 96-100%
1 Partly intelligible to familiar listeners in known context; communication partner bears the burden of the responsibility.	1 Low self-confidence/poor self-esteem/limited social integration/socially isolated/contributes to some basic and limited decisions. Cannot achieve potential in any situation.	xxx.3 Severe difficulty (high, extreme,...) 50-95
2 Intelligible to familiar listeners in context; partly intelligible in context with non-familiar listeners; single words clear, connected speech poor.	2 Some self-confidence/some social integration/makes some decisions and influences control in familiar situations.	xxx.2 Moderate difficulty (medium, fair,...) 25-49 %
3 Usually intelligible to familiar listeners in and out of context; variable intelligibility in context with non-familiar listeners; free, spontaneous speech often unintelligible.	3 Some self-confidence; autonomy emerging. Makes decisions and has control of some aspects of life. Able to achieve some limited social integration/educational activities. Diffident over control over life. Needs encouragement to achieve potential.	
4 Minor problems but intelligible to everyone; occasionally loses intelligibility at times, for example when excited or speaking against noise, etc.	4 Mostly confident; occasional difficulties integrating or in fulfilling social/role activity. Participating in all appropriate decisions. May have difficulty in achieving potential in some situations occasionally.	xxx.1 Mild difficulty (slight, low,...) 5-24 %
5 Intelligible at age-appropriate level to familiar listeners and non-familiar listeners.	5 Achieving potential. Autonomous and unrestricted. Able to fulfil social, educational and family role.	xxx. 0 No difficulty (none, absent, negligible,...) 0-4 %
		xxx.8 not specified
		xxx.9 not applicable

In Table 4 it is proposed a checklist of ICF codes for SSD, which contains the possible codes (body functions and structures, activity and participation, environmental factors) to be

used along the clinical process i.e., since clinical history to intervention. Despite some of the codes are not essential (e.g., structure of mouth) in SSD of unknown origin, we also include it because it is important in a way to establish the differential diagnosis between a primary and a secondary SSD.

CONCLUSION

Considering that ICF framework is recommended for SLPs clinical practice, the main goal with this chapter was to highlight not only the disorder but also the interaction between body structure and functions and environmental factors (positive - facilitators or negative - barriers) that have an impact on impairment and functioning levels. Thus, it is important to analyse all these components to an holistically assessment of SSD children.

In the first approaches about the use of ICF related to SLPs, some authors have been presented ICF codes that could be used to describe SSD children. However, the main code commonly used for all SSD is *articulation functions*. With the presented proposal we intend to describe phonologically based SSD using ICF codes (e.g., mental functions of language) considering the underlying phonological deficit since phonology is a language domain.

Finally it was proposed a checklist that is useful for SLPs during all the clinical process, with relevant codes that could describe children with SSD. The SLPs usually obtain information during clinical history, assessment, intervention and analyses of the efficacy and efficiency of treatment. The ICF can help the clinician in all these stages and also contribute to measure intervention outcomes.

Chapter 26

A PLAY TOOLKIT USED IN EARLY LANGUAGE INTERVENTION

Kristine Rutkowski*

Department of Speech and Language Pathology, Beaumont Health System,
Royal Oak, MI, US

ABSTRACT

Special educators often promote young children's pretend play abilities with play intervention methods because of the observed relationship between play skills and cognitive, social, and language development [1]. In a 1993 study, teachers reported that approximately 75% of children with language disorders need assistance with social play skills [2]. However, in his 1997 review of research on the symbolic play skills of children with language disabilities, M. W. Casby discovered play abilities not to be very lacking in these children [3]. Most importantly, their capabilities for using symbolic ideas in play may be similar to those of children without language disabilities, revealing "a symbolic *performance* deficit more so than a symbolic *competence* deficit. In pretend play, difficulties with language consistently get in the way of making play themes and roles explicit. Similarly, Guralnik [4] found that children with mild language disabilities tend to progress like their peers in terms of play, steadily transitioning from solitary to parallel to social play, for example, but simply taking longer to do so.

There is a growing body of evidence supporting the role not only of language proficiency in pretend play but also of pretend play in the acquisition of language [5]. Specifically, the use of a variety of props and objects, combining multiple roles and themes, and creating pretend scenarios provide the best opportunities for fostering language growth. Using clearly defined, measurable language goals, the speech-language pathologist (SLP) can promote language growth by working through a pretend play developmental hierarchy. Initially, realistic props not only expand vocabulary of common objects and their functions but also help children maintain their roles and remember their play scenario while acting out activities of daily living. As pretend play advances, props become more symbolic, often taking on more than one function during play (e.g., a box used as a boat can be flipped over to be used as a cave). The SLP progressively

* Corresponding Author Email: krutkowski@beaumont.edu.

introduces these open-ended and multi-functional items as a child's linguistic structures emerge and evolve so as to establish their relationships. Eventually, children will learn to make their own props (e.g., play dough can be shaped into a pizza) [6]. This chapter offers the SLP a play toolkit that implements a hierarchy of pretend play techniques to advance the linguistic competence of language-delayed preschoolers.

Keywords: early intervention, play, language

INTRODUCTION

As a natural activity of early childhood, play has great relevance in the field of pediatric language delays and disorders. This chapter presents a review of literature regarding the importance of play in language development and how play is used in early language intervention.

In 1969, Piaget and Inhelder [7] proposed that, as cognition is a necessity for language acquisition, so is language part of the underlying framework for human mental representational abilities. Furthermore, symbolic play is a surface manifestation of cognitive ability [7]. Therefore, development in symbolic play must parallel development in language, as each depends on the advancement of the other, for they belong to one underlying system of mental representational capacity.

The homologue model proposed by Bates [8] also supports and explains the high correlation between symbolic play and language. This model confirmed that language and cognition both developed as stems of an underlying system of cognitive operation. Therefore, child's play skills should correlate with his or her language development. The model also advocated that language development assists the development of symbolic play skills. Therefore, the two should have a direct correlation, and symbolic play development can be attributed to the language learning process.

Lifter and Bloom [9] found that advances in play and increases in receptive and expressive language emerge in concert with each other. For example, the emergence of constructing relationships between objects in play coincided with the emergence of first words. In addition, the vocabulary spurt occurred when children were learning specific relations between objects in play, such as using soap to give their doll a bath. They also found that these developments occurred simultaneously despite the variability in chronological ages the children reached these developmental achievements. Developmental advances between play and language have also been found in other studies [10, 11].

Piaget helped us to understand the relationship and connection between play and language from the child's view. "The child does not, in the first instance, communicate with his fellow beings in order to share thoughts and reflections; he does so in order to play" [12]. It is clear to all who witness children at play that they find it rewarding and motivating. Piaget [12] first divided the sequence of children's play development into three broad categories: practice play, symbolic play, and play with rules.

NORMAL DEVELOPMENT OF PLAY AND LANGUAGE

Much can be revealed about the developmental status of an infant, toddler, or young child through the observation, assessment, and evaluation of his or her play. A number of professionals have noted that play is a developmental domain that is critical to early language intervention [13-15]. In fact, the development of play demonstrates a strong relationship with the constructs of the sensorimotor and preoperational periods of cognitive development [16-18]. The SLP must be an expert in aspects of play. Play activities, behaviors, and interactions are very often some of the only performances available for observation of infants, toddlers, and children suspected of having a developmental delay. Thus, play in and of itself can be the basis of a valuable developmental assessment and intervention strategy. Rossetti [13] suggested that eliciting, observing, and describing the play of infants will give the clinician the direction needed for intervention efforts.

The early play behavior of infants and toddlers is reflective of early cognitive development. For example, the early levels of sensorimotor-exploratory play and nonfunctional relational play are reflective of the early stages of sensorimotor development, whereas later forms of play, such as functional-conventional and symbolic, indicate later stages of sensorimotor development as well as early aspects of preoperational development [14]. Some researchers believe that symbolic play is an early demonstration of young children's developing mental representation and symbolic capacity and functioning [10,12]. A number of investigators have explored the developmental relationship between symbolic play and language [16-18]. The general consensus of this line of inquiry has been that early language development and symbolic play are closely correlated. Children diagnosed with specific language impairment have been researched extensively in regard to play and have consistently been found to have delays in symbolic play [19,20]. One consensus finding has been that the younger a child with developmental disabilities is, the more likely he or she is to demonstrate difficulties in play, particularly symbolic play.

The development of communication should be assessed from birth onward as infants achieve cognitive milestones that prepare them for language. Before infants are verbal, they learn to think about means and ends. For example, they may learn to pull a cloth to retrieve a toy. They also watch their caregivers and learn. An infant may copy a caregiver's actions hours after having observed the behavior. Copying an action after a delay requires the construction, storage, and retrieval of mental symbols. These cognitive achievements reflect symbolic thought and help prepare infants to use words to communicate. Observation of infant play can help determine if they are using means and ends as well as deferred imitation behaviors within the expected time frame of development.

Infants become involved in social interaction long before they begin using words. By the end of seven months, many infants are able to turn their heads when hearing their name, smile back at another person and enjoy social play such as peek-a-boo. Joint attention and shared reference are crucial social skills that develop between nine and twelve months of age. These behaviors refer to an infant's use of communicative intent, such as smiles and gestures, to gain attention of others. It is common for an infant to repair a failed communication by trying another strategy, such as squealing or crying to gain social attention. Gestures such as pointing, smiling and gaze direction are precursors to verbal language. The use of pointing is particularly important to guide the attention of others toward objects and events.

Questionnaires and checklists for parents, such as the Modified Checklist for Autism in Toddlers-Revised (M-CHAT-R) [20] and the MacArthur-Bates Communicative Development Inventories [21], are important sources of information about an infant's gestural expression. When observations suggest delayed development, referral to a developmental pediatrician is recommended.

Some children may possess functional play skills, such as pushing a toy train around a track, but will have difficulty with symbolic play and play that involves joint engagement with others [22,23]. The emergence of symbolic play is considered an important precursor to language development [15]. During the first year of life, sensorimotor, or practice, play emerges with the child manipulating objects (e.g., mouthing, holding, banging, dropping, etc.). At approximately twelve months, the child begins to combine objects in relational play (e.g., stacking, nesting, building a tower of two blocks). Functional play (e.g., rolling or throwing a ball, drinking from a cup) also begins to occur in a child's second year. This is followed by symbolic, or make-believe, play. Symbolic play may be self-directed, such as pretending to drink from a cup, or other-directed, such as pretending to give the doll a drink. Self-directed play begins before other-directed play.

METHODS

Developmental Assessment of Play

The preceding has concerned the development of early cognition, play and language. This information is significant to speech-language pathologists involved in early intervention. This section presents a criterion-referenced, descriptive, and developmentally-based protocol for the dynamic observation and assessment of the play behavior of infants, toddlers, and young children. This protocol was developed from the wide array of studies that show the high level of validity and reliability of such measurement of play [24]. The assessment of play behavior must take place in a comfortable environment for the child and should feel as natural as possible. Present should be the speech-language pathologist, the child, and a parent or caregiver in the child's daily life. Symbolic play assessment provides the child objects with the potential to be transformed in play, that is, capable of standing in or substituting for other objects [25,26]. An assortment of objects is always presented, along with a standard set of representational objects. One possibility could be a teddy bear with blanket, bed, bottle, washcloth, and hairbrush, presented with blocks and objects of varying geometric shapes (e.g., cones, dowels, ovals, and circles), an assortment of balls, and a few sheets of paper. Either the SLP or the parent or guardian sits near the toys with the child and encourages him or her to complete a play theme (e.g., feeding the teddy bear and putting it to bed). The SLP ensures the use of both traditional, representational objects, such as the teddy bear and bed, and nonstandard objects in each play theme, occasionally encouraging substitution with the latter (e.g., giving the child a circle shape to represent a cookie, offering a sheet of paper in place of the blanket, etc.). The modeling of play, or imitative strategy, is an effective way of examining a child's zone of proximal development in the domain of play [27]. It has been repeatedly shown to elicit valid and reliable play behavior from typically developing children as well as children with a number of developmental delays [28-30]. However, the child

should also be encouraged at some point in the evaluation to play alone with the set of objects so that one may compare his or her level and quality of play when alone, when with others, and when provided various forms of scaffolding. Furthermore, given that young children with developmental delays tend to demonstrate more variability in their play performances than do normally developing children, it is especially important to assess their play abilities based on repeated observations over time [31]. Each evaluation should be videotaped for later scoring.

It is essential to evaluate a child's play against the normal developmental sequence. In 1991, Casby [25] outlined the natural development of play using four developmental phases and described symbolic play in terms of its three major functional components: agent, instrument, and scheme [25] (See Table 1.) His model supports the premise that children of different developmental levels will play differently with the same toys. Performing a behavioral assessment with this model helps the SLP quantify emerging play skills as well as those that have been mastered.

Language Intervention Using Play as an Important Domain

Pretending and language are each, at their core, modes of symbolic thought. During pretend play, a block can stand in for a school bus. In language, letters and words represent concepts, objects, or events. Children practice creating symbols as they mentally transform objects during their play. Furthermore, the more time children spend pretending, the more opportunities they create to practice using language. During pretend play, children talk more, speak in lengthier utterances, and use more complex language (e.g., future tense, interrogative clauses, conditional verbs, descriptive adjectives, mental state verbs) than when engaged in other activities [32]. Moreover, Fisher [32] reported that a kindergartener's vocabulary correlates with the amount of time he or she spent talking with peers at three years of age during pretend play.

In addition to language proficiency, pretend play contributes to a child's development of narrative abilities. The child must communicate his or her own ideas in joint creation of a play theme with their SLP. They also must integrate their SLP's ideas into a coherent narrative. Children may be better prepared to understand narratives when they have experienced or practiced similar concepts through play, such as creating descriptions to support a fantasy scenario. Through training in mature pretend play, children learn to use toys and props symbolically, develop narratives, maintain roles, and plan play scenarios from beginning to end [33].

Four key elements are needed to create the optimal early intervention treatment environment: (a) exposure, (b) deliberateness, (c) recurrence, and (d) responsiveness [31].

(a) Exposure refers to the linguistic input that is actively provided within the treatment setting. In some exposures, the child may be required to respond verbally and in others the child may be simply taking in the model of the appropriate linguistic structure. Children do not need to overtly produce or imitate language to acquire key language forms and concepts. Incidental exposures to language in a meaningful context can also be effective for language learning. (b) The SLPs are deliberate and intentional in the language that they choose. (c) Recurrence refers to the importance of repetition for children in acquiring linguistic concepts. For example, language delayed preschoolers require many opportunities to process new vocabulary. Through guided play, the highly skilled SLP provides many targeted learning

experiences. (d) Responsiveness refers to the SLP's sensitivity to the child's developing communicative competencies. Responsiveness to children and use of child-initiated themes have repeatedly been associated with language gains in children [33].

Table 1. Natural Development of Play

Phase			Age of Emergence	
Sensorimotor–Exploratory			2-4 months	Reaching, grasping, holding, rubbing, mouthing objects; repetitive pounding and hitting of objects
Relational–Nonfunctional			6-10 months	Relating objects to one another without regard for their social–conventional use (e.g., holding two or more objects, pushing objects together, stacking, bumping, nesting, offering objects to and taking objects from others)
Functional–Conventional			10-12 months	Relating objects to one another in a social–conventional manner; objects are used functionally in typical context (e.g., pushing toy car, scribbling with real crayon, putting cup on saucer, stirring bowl with spoon, feeding doll from toy bottle)
Symbolic	Agent	Self as the Agent	12-18 months	Child is both initiator and recipient of play actions (e.g., pretends to drink from a cup, pretends to talk on play telephone, brushes own hair during play cleaning/dressing)
		Passive-Other	18-24 months	Child begins to use substitute agents but does not animate them (e.g., puts cup to doll's or teddy bear's mouth, puts telephone to teddy bear's mouth and ear, brushes doll's hair)
		Active-Other	24-30 months	Child animates substitute agents (e.g., makes drinking sounds while pretending doll or teddy bear is holding the cup to its mouth, speaks for teddy bear when it is "on the phone," pretends doll is brushing its own hair)
	Instrument	Realistic Object	10-12 months	Relating objects to one another in a social–conventional manner; objects are used functionally in typical context (e.g., pretending to drink from cup, pushing toy car, coloring with real crayon) (See Functional-Conventional Phase.)
		Substitute Object	18-24 months	Substituting another object for the standard one in play (e.g., using a cone as a rocket, pretending to use a block as a cup or a dowel as a crayon)
		Imaginary Object	24-30 months	Performing an object-action scheme without the use of an actual object (e.g., pretending to talk on an imaginary telephone, pretending to drink from an imaginary cup)
	Scheme	Single	12-18 months	Carrying out a single play act (e.g., guiding toy car, pretending to drink from cup and placing it on saucer)
		Multiple	18-24 months	Carrying out sequences of two or more play acts (e.g., pretending to cut food with knife, eat off plate with fork, and then drink from cup; pretending to comb own hair and then the hair of another)
		Complex/Planned	about 30 months	Carrying out a sequence of theme-related play acts (e.g., cooking a pretend meal, setting a table for two, and then chatting with a doll over lunch)

Perhaps the most important aspect of intervention is to follow the child's lead. SLPs can observe what the child likes and dislikes and respond accordingly. They can also engage the child in theme-related conversations, ask questions, and respond to the child's ideas in a way that encourages use of targeted linguistic structures. A child may be struggling verbally during a conversation, but still be actively engaged and intrinsically motivated. At the mid-point between play and work, the child's motivation, coupled with guidance from the SLP, can create robust opportunities for language learning [34].

A language-rich treatment session involves SLPs who deliberately use language-stimulation strategies when interacting with children. Girolametto and Weitzman [34] identified eight key strategies that when used appropriately advance language development: waiting, pausing, confirming, imitating, extending, labeling, open questioning, and scripting.

- **Waiting:** Speak slowly and do not rush or dominate the conversation.
- **Pausing:** Encourage turn-taking during conversation and take care to be at eye-level with the child.
- **Confirming:** Respond to the child's interaction by commenting, smiling, and/or nodding.
- **Imitating:** Repeat what the child has stated in an affirming manner.
- **Extending:** Repeat the child's verbal responses and add verbal information. *Child:* I made a tower. *SLP:* You made a tall tower.
- **Labeling:** Label objects and object actions as well as feelings and reactions.
- **Questions:** Ask questions to encourage verbal interaction during play.
- **Scripting:** Describe the steps in a process. (e.g., "First you take the lid off the paint, then you carefully pour some in the tray, and then you can begin painting. Can you tell me what you do first?")

Table 2. Emerging Play with Corresponding Emerging Language

Emerging Play Level	Emerging Language Level
Child begins to involve relationships between objects as well as between objects and people. (Basis for object permanence; cause and effect)	<i>Content:</i> "first words" (e.g., more, in, out) <i>Form:</i> single words <i>Use:</i> joint attention
Child represents familiar activities of daily living by linking actions into a planned, multi-scheme sequence. Begins to substitute one object for another. <i>Example:</i> Child uses play block as bar of soap to wash puppy (stuffed animal), then wraps puppy in towel	<i>Content:</i> a variety of behavior-specific words (e.g., puppy, dirty, wash, dry) <i>Form:</i> single words as well as simple phrases and sentences, such as verb-object and subject-verb-object (e.g., "wash puppy", "I give bath.") <i>Use:</i> announcement of action

Girolametto, Weitzman [34] categorized these language stimulation techniques into child-oriented responses, interaction-promoting responses, and language-modeling responses. Justice [31] elaborated on the techniques: "Child-oriented responses, which are used to create and maintain a shared conversational focus between adult and child, include waiting and extending. Interaction-promoting responses, which encourage the child into active dialogue, include pausing, open questioning, imitating, and confirming. Language-modeling responses provide children with demonstrations of linguistic forms, content and use. These responses include labeling and scripting." By using language stimulation techniques during play

scenarios the SLP increases his or her responsiveness to the child's language competencies and provides the proper scaffolding to enhance language skills. In turn, the child learns to produce language that meets their individualized and targeted goals [34-39].

The steps of a language treatment session using play to extend language and new learning are listed below.

1. Arrange a setting that contains materials for play that are of interest to the child and are appropriate for the child's level of play.
2. Wait for the child to initiate an interaction about an object of interest.
3. Elaborate upon child responses.
4. Expand and extend the language and play, working on emerging objectives.

The Role of Parents and Caregivers

Parents and caregivers are often the child's first play partners. Starting in infancy, parents initiate play with children through simple games like peek-a-boo. By the child's second birthday, parents and children should regularly engage in pretend play. Early involvement from parents as initiators, directors, and partners in play serves to introduce children to more structured play by adding concepts and vocabulary that they would not be exposed to playing alone or with peers.

Table 3. Play Toolkit

Toy Complexity Continuum	
Cause and Effect	These toys are designed for a distinct effect (e.g., jack-in-the-box, ball-and-hammer toy)
Closed-Ended	Playing with these toys guides conversation along one avenue and involves a distinct beginning and end. (e.g., Mr./Mrs. Potato Head, ring stacker, puzzles)
Open-Ended	These toys never suggest completion and may lead conversation in any number of directions. (e.g., blocks, Legos, dollhouse)
Joint Play	These games are important for socialization. (e.g., follow-the-leader, duck duck goose, hide and seek, red light-green light)
Music/Song Games	(e.g., ring around the rosie, London bridges, parachute, the hokey pokey)
Turn-Taking Games	(e.g., bean bag toss, bowling games, board games)
Pretend Play	Child imagines his or herself into the play unfolding
	Performs sequences of actions within scenarios
	Role-plays with occupations, characters, animals, etc.
Play Centers/ Social Pretending	(e.g., doctor's office, grocery store, school, restaurant, camping)
Common Object Box	
Used for identifying, demonstrating, and naming objects and their functions	(e.g., farm animals, phone, keys, car, hat, shoe, sock, sunglasses, brush, ball, bowl, spoon, cup, book, etc.)
Pretend-Play Props	Boxes and containers of various shapes and sizes
	Dress-up clothes, shoes, hats, bags, and aprons
	Kitchen and household items, both toy and real (e.g., measuring cups, wooden spoons)
	Specialty items such as a doctor kit or a toy workbench and tools
	Puppets, stuffed animals, baby dolls, and caregiving items such as bottles, blankets, and diapers

Guided play can take two forms. At a very basic level, parents can enrich their child's environment by providing objects or experiences that promote language learning. In the more direct form of guided play, parents can scaffold their child's play by joining in the fun as a co-player, asking thoughtful questions, commenting on children's discoveries, and encouraging further exploration. The idea that children can benefit from parent guidance and participation in play is empirically supported.

In the clinical setting parents and caregivers are actively involved in observational learning, where they view and discuss treatment sessions with the SLP. If parents and primary caregivers are not able to attend treatment sessions, they can also learn language stimulation strategies by viewing their child's video-taped treatment sessions.

SUMMARY

In summary, play is an important domain for the assessment and treatment of delayed language development in infants and children. However, there is a long standing tradition in play research of focusing primarily on free play. The majority of studies have been done in naturalistic settings with children engaged in free play and little or no adult responsiveness or clinical intervention. The limited research concerning early play, cognitive and language development has consistently found compelling correlations. Further research is needed to examine the benefits to language delayed children of early, developmentally appropriate, intensive language therapy in a play-based environment.

Chapter 27

THE IMPACT OF PROTRACTED PHONOLOGICAL DISORDERS ON LITERACY OUTCOMES IN CHILDREN: A META-ANALYSIS

Glenda Kelly Mason* and Barbara May Bernhardt

The University of British Columbia, Vancouver, Canada

ABSTRACT

Background: The literature is equivocal on whether children with protracted phonological development (PPD) are at risk for literacy acquisition, making it challenging to provide relevant evidence-based phonological intervention. Differences in researchers' definitions of PPD have possibly contributed to the contradictory outcomes.

Purpose: The purpose of the meta-analysis was to determine the consistency of word-level literacy differences for children with and without PPD, and whether such differences are moderated by definitions of PPD.

Method: Eligible studies had measured at least one word-level literacy construct in school-aged children with and without PPD. Fifty-two evaluated papers generated 64 independent samples to examine: *Phonological awareness (PA; n = 20)*, *Word decoding (DEC; n = 17)*, *Fluency (FL; n = 4)*, *Nonword decoding (NWD; n = 9)* and *Spelling (SP; n = 14)*. Multiple regression analysis of a model that included all constructs was significant, $F(4,60) = 85.96, p < .001$ ($t = 5.71, p < .001$). Sample sizes allowed moderator testing for PA, DEC, NWD, and SP. A random effects model was used to compare *mean unbiased d* (weighted by the *inverse variance* and *Random Effects Variance Component*) on the *Q*-statistic ($p < .05$).

Results: For *unbiased Cohen's d*, *95% Confidence Intervals* and *95% Credibility Intervals* were significant for PA ($d = .85$), NWD ($d = .50$), and SP ($d = .84$), but not DEC ($d = .63$) and FL ($d = 3.04$). Cultural context was a significant moderator of SP, suggesting dialectal influences. In defining PPD, age at literacy evaluation, severity/sub-type and resolution of PPD significantly moderated NWD ($Q = 14.21$) and SP ($Q = 8.00$). Complexity of speech context, particularly inclusion of multisyllabic word (MSW) evaluations, was a significant moderator of PA ($Q = 4.85$), DEC ($Q = 4.14$) and

* Corresponding Author Email: g.kellmas@alumni.ubc.ca.

SP ($Q = 5.66$). Differences between children with and without PPD were greater in initial phases of childhood literacy compared with later phases.

Conclusion: In both initial and later phases of childhood literacy, early spoken phonological intervention seemed relevant to mitigating differences between children with and without PPD, although results were limited by the number of studies examined. To define PPD, spoken MSW phonology appeared important; a theoretically grounded continuous metric could increase study power, whether or not categorical samples are available.

Keywords: literacy, multisyllabic words, phonology, phonological awareness, phonological disorders, protracted phonological development, reading, speech delay, speech sound disorders, spelling, typical phonological development

INTRODUCTION

Over the past two decades, a number of studies have evaluated the relationship between phonological development and literacy outcomes. [1-14] Research evidence concerning the relationship between phonological and literacy development provides a foundation for clinicians providing therapy to children with difficulties in either or both areas. A meta-analysis was conducted for the current chapter on this topic, examining studies that included children with typical versus protracted phonological development. The term *Protracted Phonological Development (PPD)* encompasses various other terms in the literature, including: (a) combinations of *Phonological*, *Speech Sound*, *(In)Consistent Speech*, *(Developmental) Speech*, or *Articulation*, with one of *Disorder*, *Impairment*, *Delay*, or *Errors*; and (b) *Developmental Verbal Apraxia* or *Childhood Apraxia of Speech*. For the various studies, researchers typically sampled SLP caseloads of children with clinical diagnoses of protracted phonological development (PPD), the majority having received phonological intervention. However, an examination of the studies shows contradictory literacy outcomes that at least in part seemed to reflect differences in research methodology. These methodological differences include broader developmental considerations such as age at literacy evaluation and co-occurrence of other conditions, such as *Protracted Language Development (PLD)*. In particular, children designated with severe or persistent PPD appeared to have lower literacy outcomes than those with less severe PPD. [15-17] Thus, differences in participant selection, possibly reflecting researchers' definitions of PPD, might subsequently have contributed to the apparent contradictions.

Thus, for the meta-analysis discussed in the current chapter, a variety of methodological parameters were examined relative to age of literacy acquisition and characterization of PPD through traditional severity rankings, sub-types, resolution, and the complexity of speech context assessed. While accounting for association with PLD, therapy history and other differences in study design, the analysis aimed to (a) summarize and quantify literacy outcomes, and (b) statistically explain the variation in these outcomes in terms of age and the selected PPD parameters.

In addition to selecting participant variables related to age and characterization of PPD, relevant literacy outcomes were identified. Spoken phonology is reported to be directly related to word level literacy but only indirectly to comprehension. [18, 19] Thus, the meta-

analysis examined literacy constructs most likely connected to the cognitive organization of the speech sound system: (a) phonological awareness, (b) word decoding, (c) fluency, (d) nonword decoding, and (e) spelling. As background, the following sections describe key parameters for the analysis: characterization and evaluation of PPD and literacy constructs included, and literacy outcomes for children with protracted versus typical phonological development.

LITERACY AND THE CHARACTERIZATION OF PROTRACTED PHONOLOGICAL DEVELOPMENT

Authors have noted an overlap of PPD, Protracted Language Development (PLD), and lags in literacy attainment, [2, 20, 21] which Peterson, McGrath, Smith and Pennington (2007) [22] suggest could arise from a shared risk factor for phonological deficits, but also factors unique to each. Studies of children with PPD, in the absence of co-occurring PLD, have demonstrated inconsistency relative to literacy outcomes, with some results showing low risk, [6, 23, 24] and others, high risk. [8, 25] Researchers have reported the lowest literacy outcomes for children described as having more severe or persistent PPD. [16, 26] However, the characterization of PPD and its relative severity differ across the studies.

These differing perspectives on PPD have concerned the relevance of: (a) continuous [27] versus discrete categories of severity [28] versus sub-types of PPD [29, 30, 31]; (b) resolution or persistence of PPD [10, 32]; and (c) evaluation method with respect to both elicitation type (single-word versus connected speech), [33] and word complexity (primarily mono- and disyllabic words versus multisyllabic). [34] Word complexity might also be relevant for characterization of PPD as *resolved*; if insufficient numbers of MSWs were tested, ongoing difficulty with timing and sequencing of both syllables and speech sounds may have been missed, at least up to the age of 7 years. [35]

Further to word complexity, production of MSWs may be a key component in evaluation of the relationships between spoken phonology and literacy. Researchers have shown relationships between MSW production, phonological awareness skills, fluent word or nonword decoding, and spelling. For example, Core (2004) [37] identified positive correlations between phonological awareness scores and Percent Consonants Correct (PCC) on a MSW naming task in 5- and 6-year-olds. Larrivee and Catts (1999) [26] observed that MSW and nonword repetition in children with severe PPD at the end of kindergarten, predicted outcomes in decoding and nonword decoding at the end of grade 1, and explained the greatest variance in decoding (including MSW *DEC*) in grade 3. [38] For ages 5 to 8;7 years, PCC of MSWs explained a larger significant unique variance in composite real and nonword decoding when included in a model with composite phonological awareness and lexical retrieval scores. [39]

In addition to such differences in characterization of PPD, diversity in terms of literacy construct and/or measurement method are relevant in evaluation of the relationship between PPD and literacy.

CHARACTERIZATION OF LITERACY AND THE INCLUDED CONSTRUCTS

In terms of literacy evaluation, the stage of acquisition is relevant. In earlier elementary school, formal literacy instruction begins and focuses chiefly on the letter names, sound-symbol correspondence and basic spelling patterns needed to decode frequent words. In later elementary school, literacy instruction places a greater emphasis on extracting meaning from text, which comprises words with decreasing frequency. In the high school years and beyond, students must decode and comprehend infrequent multimorphemic words, and comprehend increasingly abstract text in the context of less explicit literacy instruction. [40] Theories of literacy strive to account for student advancement across these stages, with word level literacy considered a foundation for all of them. [41]

Most theories assume spoken and print language to be connected through some aspect of phonological processing, particularly the representation of smaller speech units by letters. [42, 43] The commonly described *Dual Route* models suggest that reading or spelling words involves two separate cognitive procedures. [44, 45] The models aim to explain how knowledge of word sub-units (phonological awareness) enables reading of familiar versus unfamiliar words (word and nonword decoding) and their orthographic encoding (spelling). However, the constructs and evaluation of phonological awareness, decoding and spelling have also varied across studies, discussed as follows.

Phonological Awareness (PA)

Phonological awareness (PA) refers to knowledge (implicit and explicit) that words are composed of sub-units (e.g., syllable, onset, rhyme, phoneme), and to the ability to consciously manipulate these units mentally. [4, 46, 47] Studies have shown robust relationships between word level literacy and PA, [18, 48, 49] with a minimum proficiency deemed necessary for acquiring phonological to orthographic correspondences for both monosyllabic, [50] and MSW word recognition. [51]

Characterization and evaluation of PA have differed in conjunction with children's developmental level. Task characterization has varied in terms of levels of meta-cognitive awareness and working memory, language recognition versus production, and the size of phonological units. [13, 46, 52, 53] Studies have utilized standardized tests, [1, 39, 47] nonstandardized tasks, [12, 36, 53] or a combination thereof. [8, 11] Rhyme and onset matching tasks have predominated through age 6 years. For 7- to 8-year-olds, segmenting and blending have been common, sometimes of syllables and onsets but more often, phonemes. Phoneme manipulation tasks have frequently been administered from age 7 years, initially elision, and progressing to phoneme reversals at ages 10 through 13 years.

Decoding (DEC) and Fluency (FL)

In terms of word reading, Ehri (1992) [49] described the relationship between dual routes for recognizing words, i.e., *recoding* or *decoding (DEC)*, and automatic sight recognition,

fluency (FL). *DEC* is assumed to rely on intermediate application of grapheme-to-phoneme rules for translation of orthographic representations into suprasegmental structure and phonological segments, before accessing meaning. [41] As reading proficiency increases, readers learn progressively larger orthographic chunks, including syllabic patterns, with few exposures to a word. This enhances *FL*, suggesting stronger and faster cognitive connections from orthography to phonology and meaning. [49] All orthographic words may in fact connect to meaning and pronunciation concurrently, [44, 54, 55] emphasizing the foundation of accurate spoken phonology for translating print into speech. [56, 57]

Nonword Decoding (NWD)

In *nonword decoding (NWD)*, knowledge of grapheme-to-phoneme rules is required to read pseudo words, and so is largely accomplished without the contribution of meaning. [54] As children develop representations of larger chunks of orthographic patterns, however, word neighborhoods might aid in recognition of parts of nonwords. [41] In child literacy development, the importance of *NWD* has come from evidence that acquisition of phoneme-to-grapheme correspondences depends on factors beyond phonological awareness (e.g., some children have performed well on *PA* tasks but not on tasks involving phonological to orthographic correspondence). [50]

In comparison with the variety of *PA* assessments, *DEC* and *NWD* have been primarily assessed on word lists from standardized tests, [53, 58] and infrequently on nonstandardized tasks. [2, 58] Standardized tests of *DEC* have been created in several contexts: North America, [8, 14] Great Britain, [2, 31] Australia, [4] and New Zealand. [5] Uniquely, Overby et al. (2012) [7] determined the ecological validity of measures from the Templin Archive (2004) of longitudinal data from 1960-1972. Irrespective of country, the *Word Attack* subtest of the *Woodcock Reading Mastery Test* [59, 60] was the standardized measure used to evaluate *NWD*. [1, 5, 14, 24] The few studies investigating *FL* varied as to whether primary or secondary data were collected, from a small sample of word and nonword list evaluations [12] to a large database of passage reading assessments, [10] respectively.

Spelling (SP)

Turning to the final construct, *spelling (SP)* requires representation of spoken words with conventional orthography. [61] Neuroimaging studies about accuracy and reaction time for regular, irregular and nonword *SP* recognition have supported both phonological and lexical routes for spelling. [62] Because accurate, as opposed to phonologically legal spelling, must be generated, [45, 63] *SP* possibly relies on more detailed, explicit phonological to orthographic connections than reading. Ehri (1992) [49] considered such full alphabetic skill to be hierarchically organized, with automaticity gained from strong long-term memory connections between *SP* and pronunciation. Representing words in print is further taxed by demands for coordination with fine motor output, integration with morphosyntactics and, if in text versus list form, organization of ideas.

In studies of children with PPD, *SP* has been uniformly assessed using word dictation but with various measures, including recently standardized tests, [6, 36, 64] older standardized tests, [2, 4, 7, 65] and nonstandardized tasks. [1, 5, 32]

LITERACY OUTCOMES

Keeping in mind the diversity in characterization and evaluation of PPD and literacy, the following section provides an overview of literacy comparisons between children with and without PPD as background for the meta-analysis. The term PPD will pertain to any diagnosed history, whether or not considered ongoing at the point of literacy measurement. Thus, the groups studied will be stratified only by age to highlight progression with literacy.

Phonological Awareness (PA)

Studies of *PA* have compared children with typical versus protracted phonological development in the early and late elementary school years, i.e., *learning to read* and *reading to learn* phases, respectively. [40] Preschoolers with PPD (3- to 6-year-olds), have shown lags on composite score analyses, [11, 37, 46] and awareness or matching subtests at the rhyme and word initial phoneme levels, [4, 12, 53] with significance on whole word segmentation and blending. [52, 47] In late preschool, at 5 to 6 years of age, persistent PPD has had the strongest relationship with *PA* and a moderate *effect size (ES)*. [11]

At school age, studies have focused on the *learning to read* phase. Six- to eight-year-olds with PPD history have shown equivalence to children with TD on rhyme and phoneme awareness but significantly lower scores on various phoneme segmentation and blending tasks. [13, 58, 66] On the latter tasks, children up to age 9 years have scored within the average range, yet shown significant differences compared with TD children. [1] Peterson et al. (2009) [8] also found a significant difference and large *ES* on a *PA* composite for 7- to 9-year-olds; furthermore, controlling for nonverbal IQ, persistent PPD at age four years predicted ongoing *PA* difficulty.

Fewer studies have compared *PA* outcomes for older school-aged children or adolescents with PPD history versus typical development. Also uncommon are studies evaluating longer words or manipulation tasks, such as elision or substitution of segments. School-aged children with and without PPD, predominantly 8- to 11-year-olds, have performed equally well on blending and segmentation tasks but with ceiling effects. [6, 36, 38] On more advanced *PA* tasks of manipulation, such as reversed phoneme segmentation or Pig Latin, adolescents with PPD have lagged behind TD peers, irrespective of significance levels. [2, 9] However, the relationship of such tasks to literacy is unclear.

Overall, children with PPD history from preschool through adolescence appear to lag behind TD children on *PA* composites or subtests of increasing complexity. *Effect sizes* suggest moderate to large differences. Finally, PPD in early childhood is associated with lower *PA* outcomes, which in turn have predicted ongoing *PA* difficulty.

Decoding Skills: Word Decoding (DEC), Nonword Decoding (NWD) and Fluency (FL)

Outcomes for decoding skills have been reported for the *learning to read* phase, and to a lesser extent, the *reading to learn* phase. In each phase, whether or not significant, lower scores have been reported for children with PPD than for those without. In the initial phase, despite ceiling effects, 5- to 7;6-year-olds with PPD have shown significantly lower scores on *DEC* and *NWD* than TD peers. [2, 58, 67] Other studies have found average, but lower scores for children with PPD compared with those of their TD peers, with both significant, [7] and non-significant differences. [4, 23, 24]

Within wider age ranges, 6- to 9-year-olds with PPD have also had average achievement on *DEC*, [1, 8] and in comparison with children with TD, superior performance has been reported for *NWD* subsequent to PA therapy, with a large *ES*. [5] More broadly, small samples of school children aged 7 to 11 years showed significantly lower *DEC* scores, [31, 65] but using an upper limit of 13 years, *DEC* and *NWD* have been within average. [14, 68] Adolescents aged 12 to 17 years have also obtained average but consistently lower scores on *DEC* and *NWD*. [36]

A final aspect of decoding is *fluency*. For children with PPD, few studies of this construct exist, and those that do have focused mainly on the *learning to read* phase. For 5- to 6-year-olds with PPD, performance on words and nonwords has been in the average range, but significantly lower for the nonwords. [12] Meredith (2002) [6] found average word *FL* for 8- to 9-year-olds with PPD but with significant differences and large *ESs* compared with children with TD. [6] Finally, by grades 2 to 3, *FL* in connected text has been negatively correlated with persisting PPD. [8, 10]

To summarize the findings for the decoding attainment of school-age children with PPD history, average performance has been demonstrated on *DEC*, *NWD* and *FL*, although this performance may lag behind that of groups with TD. As was implied for PA, *ESs* suggest moderate to large magnitudes of difference for decoding, nonword repetition and fluency.

Spelling (SP)

More consistent results have been reported regarding *SP* proficiency, where children with history of PPD have performed significantly lower than their TD counterparts, [2, 7, 32] even during adolescence. [36, 68] A history of PPD has also predicted unique significant variance in *SP*. [1] Nonetheless, some studies have shown performance within the average range for children with history of PPD. [6, 7, 68]

MOTIVATION AND QUESTIONS FOR THE META-ANALYSIS

Assuming equivalence between children with and without PPD in other developmental domains, the overall disadvantages in word level literacy of children with PPD are important for at least two reasons: (a) decoding of longer infrequent words and comprehension of

increasingly abstract text might become more challenging, and consequently, (b) the range of available educational, career or employment choices might be narrower than for TD children.

The synopsis above suggests that overall, children with PPD history have lower literacy outcomes than their TD peers, even when their scores fall within the average range of tests normed on typically developing children. However, questions remain concerning the scale of difference for the selected word level constructs, the relative contributions of earlier versus later phases of childhood acquisition (*learning to read* versus *reading to learn*), and characterization and evaluation of PPD. A meta-analysis was thus undertaken in order to address those topics in terms of the following questions:

1. Are children with PPD consistently disadvantaged in word level literacy acquisition compared with TD peers, and if so, to what extent? Moderate to large magnitudes of difference were predicted between children with and without PPD, for each literacy construct: *Phonological Awareness*, *Decoding*, *Nonword Decoding* and *Spelling*, with the greatest group differences in *Spelling*.
2. Are there between-group differences in both the early (*learning to read*) and later (*reading to learn*) childhood phases of literacy acquisition? Between-group differences were predicted in both phases.
3. Are there differences between school-aged children with and without PPD that vary according to the characterization of PPD? The degree of protracted phonological development at time of literacy measurement was predicted to explain differences between groups whether envisioned as discrete categories of severity and sub-type, or resolution of PPD. Variation in methods used to characterize PPD, in terms of context of assessment, (i.e., MSWs and connected speech) was predicted to explain between-group differences.

METHOD

This section first briefly describes the meta-analytic objectives, and then outlines steps for the current analysis, including: search methods and study inclusion criteria, coding of moderators and reliability, data selection and transformation for *effect size (ES)* calculations, and methods for obtaining descriptive and analytic results.

Meta-Analysis Objectives

Meta-analysis provides a statistical synthesis of comprehensive research findings obtained from different study designs and/or from sub-sets of data within studies. [69, 70, 71] The included studies/data serve as the participants upon which hypotheses are tested. *Effect sizes* (the magnitude and direction of actual differences) calculated from the selected data are standardized in order to aggregate and compare them. The method involves transformations, weighting and fitting of data to a statistical equation that takes into account study influence by sample size. These processes address bias arising from the sampling of studies, and/or the populations from which samples within studies are taken. While primary investigations

explain variability in results according to dependent variables, meta-analyses examine independent variables (moderators) of interest and potentially specify gaps in research.

Study Selection

To obtain a comprehensive sample of studies of literacy outcomes for children with PPD, search terms included school age/ children/ childhood/ SSD/ speech/ articulation/ phonological/ disorders/ disabilities/ impairment / apraxia of speech/ phonological awareness/ literacy/ decoding/ word decoding/ word recognition/ fluency/ nonword decoding/ spelling/ comprehension/ reading/ dyslexia. The search for peer reviewed primary articles, conference proceedings and dissertations for any year included the main speech-language pathology, applied linguistics and education databases: Academic Search Complete, Cochrane Systematic Reviews, Communication and Mass Media Complete, CINAHL (Cumulative Index to Nursing and Allied Health Literature), Dissertation Abstracts International, Education Full Text (H.W. Wilson), Education Index Retrospective: 1929-1983 (H.W. Wilson), Education Research Complete, ERIC (Education Resource Information Center), Linguistics and Language Behavior Abstracts (LLBA), PsycARTICLES, PsycBOOKS, PsycINFO, PsycEXTRA, and Pub Med (1946-present). Subsequently, 5128 abstracts were reviewed (including duplicates in the various databases), from which 52 papers were evaluated, and their reference lists searched for additional candidates.

Inclusion Criteria

Inclusion criteria were relevant to aspects of study design, participant socio-behavioral characteristics, and available *effect size* (*ES*) data. Included studies measured at least one literacy construct of interest, in school-aged monolingual English-speaking children with PPD history (without other notable developmental conditions) and a typically developing comparison group (TD).

With respect to data availability, *ES*s (or means and standard deviations from which to calculate *ES*s) either had to be published or obtainable from authors. Thirty-four studies, reported from 1980 to 2012, met the inclusion criteria, generating 64 independent samples distributed across constructs accordingly: *PA* $n = 20$; *DEC* $n = 17$; *FL* $n = 4$; *NWD* $n = 9$; and *SP* $n = 14$. A total of 4007 children from 4 to 17 years old (1496 with PPD and 2511 with TD) was represented, with construct and corresponding sample sizes as follows: *PA* $n = 994$ ($n_{PPD} = 527$, $n_{TD} = 467$); *DEC* $n = 1717$ ($n_{PPD} = 410$, $n_{TD} = 1307$); *FL* $n = 10455$ ($n_{PPD} = 1520$, $n_{TD} = 8935$); *NWD* $n = 479$ ($n_{PPD} = 206$, $n_{TD} = 273$); and *SP* $n = 817$ ($n_{PPD} = 353$, $n_{TD} = 464$). Few age spans were as narrow as one year: an age span of 3 to 3½ years and 4½ to 5½ years was reported by 50% and 40% of studies, respectively; in one study, the range was 6½ years.

In some cases, data clarifications and adjustments were needed before *ES*s could be determined. Clarifications included: (a) establishing sample independence in Holm et al., 2008 [4] (A. Holm, personal communication, November 22, 2011); (b) verifying a reading correlation value in Overby et al., 2012 [7] (M. Overby, personal communication, February 27, 2012); and (c) obtaining unpublished data for Apel & Lawrence (2011) [1], Sutherland & Gillon (2006) [47], and Wellman et al. (2011) [14]. Catts (1991) and (1993) [23, 24] were

treated as one longitudinal study because the second study followed up on the sample of children in the first. Finally, to improve equivalence of data and reduce the number of inferential tests for *PA*, composite scores were calculated if unreported, e.g., Peterson et al., 2009. [8]

Coding of Included Studies

Coding was pertinent to the inclusion criteria and also to: publication identity, participant socio-behavioral attributes, literacy measures, and PPD characterization with consideration of co-occurring PLD. Coded socio-behavioral attributes were those used by researchers to equate comparison groups (and in some cases, tested for equivalence post hoc). [2, 11] Attributes considered were age, and one or more of the following: grade, classroom, IQ, language skills, reading/spelling level (when not a dependent literacy variable), ethnicity and SES/maternal education. Specific tests of each literacy construct were also coded.

In relation to characterization of PPD, exclusion of additional studies on the basis of potential bias arising from co-occurring PLD was also judged. The proportion of co-occurring PLD within included samples was coded for and language evaluation methods were reviewed. Whereas a small percentage of studies referred to a clinical history without PLD diagnosis, 85% directly assessed language performance across a variety of comprehension and/or production skills. In the latter case, co-occurring PLD was defined by accepted clinical criteria (1.5 SD below the mean or criterion cut-off) and/or a significant post hoc comparison between groups with and without PPD. Analysis of these methods for identifying co-occurring PLD suggested that a third of included studies (40% of those studies that directly evaluated PLD) reported no more than 25% co-occurring PLD. The coders agreed, therefore, that there was reasonable control for confounding of literacy outcomes by co-occurring PLD, and no further studies were excluded.

Following examination of co-occurring PLD, PPD was characterized in terms of status and evaluation parameters. Statuses at time of diagnosis and at literacy measurement were coded with respect to: (a) traditional severity ratings, (b) subtype frameworks such as pattern consistency or *Childhood Apraxia of Speech* (CAS), and (c) resolution or persistence. With respect to resolution, mixed groups were coded as persistent if investigators reported few children with resolved PPD (e.g., 3 of 15 in Catts, 1993 [24]; 7 of 86 in Peterson et al., 2009 [8]). Coded evaluation parameters were the specific testing methods used, elicitation type (single words, connected speech) and word complexity (mono- and disyllabic versus multisyllabic). Coding of word complexity took into account that: (a) prominent stress occurs more commonly on word-initial syllables in English disyllabic (DSW) words; (b) adult-like production of DSWs with weak (unstressed) initial syllables presents a notable challenge in childhood phonological acquisition; [27] and (c) DSWs with initial unstressed syllables and MSWs, defined as three or more syllables, are infrequent on common norm-referenced tests (occurring less than 10% of the time). [35] Consequently, a dedicated corpus of MSWs was coded whenever researchers evaluated an independent set of at least ten DSWs with initial unstressed syllables and/or MSWs (the minimum number used in the included studies). [29, 72] Tests with fewer than 10% complex words, e.g., the often-used *Goldman Fristoe Test of Articulation* (GFTA), [73] were coded for mono- and di-syllabic words; otherwise, a mixture

of mono-, di- and multi-syllabic words was coded. MSWs were not coded for connected speech elicitation, because type/token frequencies were unreported.

Reliability of Coding

Two Canadian certified and registered speech-language pathologists coded study moderators and *ES* data: (a) the first author, a doctoral student with dedicated coursework in meta-analysis and over 30 years of clinical experience, and (b) an SLP, holding a Master's degree with completed research project relating to PPD, and four years of clinical experience. Coding definitions were discussed, and when not agreed upon, the first author's coding stood. The correlation and degree of agreement for multiple coders rating multiple moderators was estimated with the *intraclass correlation (ICC)*. [74] Because both coders coded all moderators, and to allow greater generalizability to other pairs of coders, the *ICC* was tested in a fully crossed random effects design. High reliability on all study moderators was indicated, $ICC(2,1) = .976$ [CI = .974-.978]. Regarding data selection and *ES* calculation reliability, differences were discussed to achieve 100% agreement.

Determination and Analysis of *ES*s

This section outlines the methods for the next three stages of the meta-analysis, beginning with obtaining *ES*s for the selected data, followed by the descriptive and then inferential analyses. The descriptive analysis applies to the distribution and weighting of *ES*s. The inferential process includes multiple regression analyses (MRAs) for identifying significant variability in any literacy construct, and subsequent testing of that variance on the selected moderators.

Calculation of Cohen's *d*

To allow examination of the standardized magnitudes (thus independent of sample size) of actual mean differences between groups with and without PPD, *Cohen's d* was the selected *ES* for the meta-analysis. To insure independence of samples, one *ES* per literacy construct per study was chosen. For calculation of *d*, weighted means and/or pooled standard errors (i.e., proportionate to comparison group sizes) were derived from available raw scores, gains, percentiles, and standard scores. Because the value of *d* tends to be upwardly biased in small samples, by applying conversion formulas, [75] accuracy was adjusted to *unbiased d*, which was used in all subsequent analyses.

Descriptive Analysis

In the first step of the descriptive analysis, distributions of *unbiased d* were assessed through construction of funnel plots, which allow for the greater variance in small samples, reducing the number of outliers. The second step was to adjust *unbiased d* to obtain more

precise estimates of the population *ESs*, and adjust study influence relative to sample size. To obtain this *weighted d*, *unbiased d* was weighted by the inverse variance. [75] The adjustment contributed to retention of outliers, and thus, all of the data in the inferential analyses. The magnitude of *weighted d* was interpreted according to Cohen's (1988) [76] conventions (small ≥ 2 ; medium ≥ 5 ; large ≥ 8). For the *z-test* of the significance of each study *ES* and the mean for each construct, 95% *Confidence Intervals (CI)* were constructed.

Inferential Analysis

Moving to the inferential analysis, two MRAs ($p < .05$) were conducted to determine if any of the constructs had significant variance to explain by the testing of moderators. In the first regression, a fixed effects model (which assumes that all possible studies are included) analyzed *weighted ds*. However, the analyzed studies were likely estimating for different populations because of: (a) a small sample of *ESs* per construct; (b) limitations in attaining sample size power through random sampling of children with PPD; and (c) variation in parameters used to equate comparison groups. The MRA was therefore repeated on the *mixed weighted ESs* using a random effects model (which assumes that all possible studies are not included). This entailed re-weighting of the *weighted ds* by adding the *Random Effects Variance Component (REVC)*, i.e., the variability across possible populations of study samples. The additional weighting yielded a more stringent regression because the resultant 95% *Credibility Interval (CredInt)* for the *mixed weighted d* could be expected to increase (more likely to contain zero), potentially decreasing the number of significant *ESs*.

Testing of Moderators

In this last stage of the meta-analysis, for each significant literacy construct, two groups of *mixed weighted ESs* were compared on a selected moderator by a Q-ANOVA (based on *Chi-square* for categorical variables, similar to 1-way ANOVA), $p < .05$. The result indicated whether the grouping variable (moderator) accounted for significant variability and whether there was significant variability (heterogeneity) remaining to be explained by other moderators. This process of testing moderators continued until either: (a) homogeneity of variances (no additional significant variance) was reached; (b) all moderators of interest had been tested; or (c) there were insufficient *ESs* (for the current meta-analysis, $n < 3$) to allow further meaningful analysis.

To address more extraneous influences of variables commonly associated with behavioral research, representative study design moderators were distinguished from participant characteristics directly pertinent to the research questions. Study design characteristics comprised: (a) cultural context, to account for the various countries in which included studies were conducted; (b) gender balance, because of conflicting information about gender differences in phonological development, [77, 78, 79], (c) sample size, because groups with TD were frequently larger than those with PPD; and (d) literacy evaluation type, due to variation in tests used to measure a given construct.

Directly related to the research questions were the participant moderators, including mean age (within one-year intervals) and characterization of PPD at the point of literacy evaluation.

The mean age grouping variable compared early (*learning to read*) with later (*reading to learn*) childhood literacy acquisition whereas characterization of PPD encompassed: (a) resolution, i.e., groups with and without a proportion of children with resolved PPD, (b) severity/subtypes, i.e., moderate to severe, with or without mild PPD, and (c) elicitation contexts (single words versus connected speech, and word length by syllables, i.e., MSWs).

Further to severity/subtypes, those making reference to consistency (*delay*, *consistent* and *inconsistent*) were coded for infrequently. To increase available sample sizes for testing of moderators, the coders compared descriptions of these subtypes (B. Dodd, personal communication, January 7, 2013) with traditional severity ratings (*mild*, *moderate*, *severe*) and agreed to collapse: *delay* with *mild*; and *consistent* and *inconsistent*, with *moderate* to *severe* and *severe*. *Child Apraxia of Speech* was also included in the latter group. Bias was considered minimized by: (a) the small number of samples in the *mild* category coded for *delay* (*PA*, *NWD* and *SP* [$n=18$]; *DEC* [$n=19$]); and (b) grouping the *moderate to severe* and *severe* codes in any tests of moderators. Small sample sizes of groups coded with more severe or persistent PPD precluded separate analyses.

RESULTS

The *effect size* data (*Cohen's d*) were examined to address the research questions concerning word level literacy acquisition of children with PPD in comparison to peers with typically developing phonology (TD). In this regard, the descriptive analysis first outlines to what extent children with PPD are disadvantaged in word level literacy. Moderate to large magnitudes of difference were predicted for each literacy construct, with the greatest in *SP*. Findings pertaining to these predictions will be discussed by construct in the following order: *Phonological Awareness (PA)*, *Word Decoding (DEC)*, *Fluency (FL)*, *Nonword Decoding (NWD)* and *Spelling (SP)*.

In the subsequent section concerning inferential results, MRAs of *ESs* and assessment of study design moderators are presented first. Then, the research questions about literacy acquisition in children with and without PPD are addressed. Regarding stage of literacy acquisition, differences were expected in both early and later stages, with larger differences in the later stage, assuming a slower developmental trajectory in children with PPD. [10] The final question addressed potential differences according to the characterization of PPD. [36] A first prediction was that degree of PPD at time of literacy measurement would explain variation in literacy outcomes, whether defined in terms of severity and sub-type, or by resolution. Second, it was predicted that speech evaluation method would also moderate word level literacy outcomes and support the need to assess phonologically complex speech contexts (i.e., MSWs and connected speech) in school-aged children.

Descriptive Analysis Results

Relevant to the descriptive results are the visual displays of data in funnel and forest plots for the *unbiased d* and *mixed weighted ds*, respectively (see Appendices A and B). Data for four literacy constructs, *PA*, *DEC*, *NWD* and *SP*, are displayed in both plots, but because the

sample for *FL* was small ($n = 4$), only the related forest plot was constructed. The funnel plots depict the distributions of *unbiased d*, from which outliers can be visualized. The treatment of outliers was to adjust *ES* accuracy through weighting by the inverse variance, enabling retention of all data in the statistical analysis. For the *mixed weighted ds* (weighted additionally by the *REVC*), the forest plots convey the *ES* values, the 95% *Confidence Intervals* (*CI*s) of each study and of the mean *d*, with associated 95% *Credibility Intervals* (*CredInt*s). The forest plots confirmed moderate to large effect sizes between children with and without PPD on the literacy constructs, as follows: moderate for *DEC* and *NWD* and large for *PA*, *FL* and *SP*. The means for *PA*, *DEC*, *NWD* and *SP* were significant but only that for *PA* was generalizable to other populations of studies. Further details concerning these findings are reported below.

With reference to the funnel plots for *PA*, *DEC*, *NWD* and *SP* (Figure A1 to Figure A4, respectively), distributions were normalized using logarithmic lines, setting limits at three standard deviations. In the subsequent assessment of outliers, attention was given to negative values of *unbiased d*, whereby children with PPD outperformed those with TD, a less expected outcome. Negative *ES* outliers were observed in the plots for *DEC* and *NWD* only and were few, specifically: *DEC* = 2 ($n = 17$); *NWD* = 3 ($n = 9$). In the raw data for *FL* ($n = 4$), there was one negative value. However, because the weighting procedures were expected to adjust these values and all other outliers sufficiently, negative outliers were retained in the subsequent analyses. This procedure avoided selective data removal and consequent reduction of construct sample sizes.

The respective forest plots for *PA*, *DEC*, *NWD*, *SP*, and *FL* are displayed in Figure B1 to Figure B5, respectively, and are referenced below. The forest plots show the range of the *mixed weighted d* for each included study, and the *mean* for the construct, with the interval estimates of significance (95% *CI* and 95% *CredInt*). For *PA*, (see Figure B1) two study *CI*s were without significance; however, the *CI* and *CredInt* indicated a significant large mean ($d = 0.85$; range = -0.02 to 7.90). For *DEC*, (see Figure B2), five study *ds* were not significant but the *CI* suggested a significant moderate mean ($d = 0.63$; range = -1.51 to 4.99). For *NWD* (see Figure B3), three study *ds* were without significance but the *CI* was significant for the moderate mean ($d = 0.50$; range = -1.25 to 3.38). Regarding *SP*, Figure B4 showed nonsignificant *ES*s of four studies but a significant *CI* for the large mean ($d = 0.84$; range = -0.66 to 4.67). For *FL*, Figure B5 demonstrated the significant large *ES* for the study by Puranik et al. (2007) [10]; however, the mean for the construct was not significant ($d = 3.04$; range = -0.005 to -0.09).

In summary, for all literacy constructs, predictions of moderate to large differences were substantiated between the mean *mixed weighted ds* for groups with and without PPD. The largest *ES* was predicted for *SP*; however, the largest was found for *FL*, and the *ES*s for *PA* and *SP* were equivalent. In spite of the greater difficulty attributed to *NWD* than *DEC*, a moderate mean effect was obtained for both constructs. Concerning generalization, the mean *mixed weighted d* for the small *FL* sample was without significance. In contrast, the 95% *CI*s for all other constructs suggested significant means, but only the 95% *CredInt* for *PA* indicated that the *mean ES* was also generalizable to other possible populations.

Inferential Analysis Results

Results for the Multiple Regression Analysis (MRA)

Two separate MRAs were conducted to determine if there was significant variance ($p < .05$) among the *ESs* of any of the constructs to allow testing of moderators. Both a fixed effects model (which assumes that all possible studies were included), and a random effects model (which assumes that the analyzed studies were estimating for different populations) were implemented for the *weighted* and *mixed weighted ds*, respectively. A theoretical model was constructed that considered the incremental demands on phonological and orthographic knowledge, plus availability of semantic cues. This model was used to establish a hierarchical order for entering a single literacy construct at each step: *PA*, *DEC*, *FL*, *NWD* and *SP*. In the first regression, the R^2 change (*ES* for MRA) reached significance once *NWD* was entered, $F(3,60) = 6.17$, $p = .001$. The addition of *SP* also resulted in a significant model, $F(4,60) = 4.55$, $p < .003$; however, the R^2 change was not significant, indicating that only *NWD* accounted for the significance of the last two models.

In the second regression of the *mixed weighted ds*, the R^2 change for all four models was significant (see Table 1). The constant, *PA*, was also significant, $t = 5.71$, $p < .001$. Therefore, all of *PA*, *DEC*, *NWD* and *SP* had additional variance to explain for the moderator analysis. Because the sample size for *FL* was too small to make meaningful comparisons on the moderators, it was not examined further.

Table 1. Model Summary for Multiple Regression of *mixed weighted d* for the Literacy Constructs

Model	R	R ²	Adj R ²	Se	ΔR^2	ΔF	df1	df2	Sig ΔF
PA*DEC	.345	0.119	0.105	1.87	0.12	8.35	1	62	0.005
PA*DEC*FL	.475	0.226	0.2	1.77	0.11	8.44	1	61	0.005
PA*DEC*FL*NWD	.534	0.285	0.249	1.71	0.06	4.96	1	60	0.03
PA*DEC*FL*NWD*SP	.842	0.709	0.689	1.10	0.42	85.96	1	59	0

Note. PA = Phonological Awareness. DEC = Word Decoding. NWD = Nonword Decoding. FL = Fluency. SP = Spelling.

Result for the constant, PA: $t = .571$, $p < .001$.

* $p < .05$.

Results for the Testing of Moderators

The analysis next concerned the significance of the moderators on the *Q*-tests of between-groups variances for the mean *mixed weighted ds* ($p < .05$), first for study design and then participant characteristics. For each literacy construct, these results and those for the *Q*-tests of homogeneity of variances within groups ($p < .05$) are presented in detail in Appendices C to F. Although the intent was to test all literacy constructs (*PA*, *DEC*, *NWD* and *SP*) on all moderators, constructs with insufficient samples of *ESs* were excluded from the analysis.

Study design moderators were initially tested aside from the participant characteristics, in order to address selected factors known to influence developmental behavioral research: cultural range, proportion of male participants, sample size and specific literacy measures used. The subsequent sequence of testing participant characteristics concerned differences in literacy outcomes in earlier versus later childhood literacy phases, and characterization of PPD in terms of severity/sub-types or resolution, and level of speech complexity evaluated (single words versus connected speech, and MSWs).

Results for Study Characteristics

Table 2 summarizes the analyses of the study characteristic moderators. These moderators appeared to have minimal influence on the outcomes for the literacy constructs, with some exceptions for *SP*. For this construct, two moderators were significant, i.e., cultural context and measure used.

With regard to the first moderator, cultural context, included studies were primarily from the United States and England, with a limited number from New Zealand, Scotland and Canada. All constructs were tested on cultural context, with nonsignificant results, with the exception of *SP*. For this construct, there were differences between the United States and England, whether or not either country was grouped with New Zealand, Scotland and/or Canada.

The next moderator, gender ratio, was examined to ascertain whether literacy outcomes reflected proportions of girls and boys in the study. Balanced gender was defined as near 50%, but no more than 60% male, to allow latitude for the greater likelihood of protracted speech and language development in boys. The gender moderator was not significant for groups with PPD, and homogeneity was reached on one construct, *SP*.

Table 2. Study Moderators Tested and Significance across Constructs

Moderator	Groups Tested	PA	DEC	NWD	SP
Cultural Context	US vs England (with/without other ^a)	✓	✓	✓	*
Proportion Male Participants					
PPD	Near 50% to 60% vs 61 to 70%+	✓	✓	✓	✓
TD	Near 50% to 60% vs 61 to 70%+	*	✓		*
Sample Size					
ΠPPD	4 to 25 vs 30 to 98	✓	*	*	*
ΠTD	4 to 44 vs 98 to 815	*	✓	*	*
Measures of Construct ^b	Standardized & Nonstandardized	✓	✓		*
	Specific Standardized		✓		✓

Note. PA = Phonological Awareness. DEC = Word Decoding. NWD = Nonword Decoding. SP = Spelling. PPD = Protracted Phonological Development. TD = Typical Development.

^aOther = New Zealand, Scotland and/or Canada. ^bBecause NWD was typically evaluated with the Woodcock Reading Mastery Tests (WRMT; Woodcock, 1987, 1998), no test of moderator was available.

* $p < .05$.

Regarding groups with TD, gender ratio was balanced in all but one study of *NWD* ($n=9$), and so was not tested. Of the three remaining constructs (*PA*, *DEC* and *SP*), only *PA* was significant, comparing respective large and moderate *ESs* for balanced and unbalanced gender. Unexpectedly, the larger *ES* pertained to groups with smaller as opposed to larger proportions of boys. Considering the small number of *PA* studies lacking gender balance (4 of 18), gender ratio did not appear to have a substantial influence on group literacy differences in the included studies.

With respect to the third study design moderator, sample size, significant results would have confirmed the expectation that larger *ESs* are related to larger samples. In the tests of the sample size moderator, comparisons of smaller with larger groups of children (both TD and PPD), reached significance for all constructs, with two exceptions: (a) *PA*, for children with PPD, and (b) *DEC*, for the group with TD. With respect to children with PPD, across literacy constructs, the mean *weighted ds* for smaller samples ranged from small to moderate but were compared with consistently large *ESs* in larger samples, as expected. Regarding typically developing children, *ESs* were more various; in smaller samples, they ranged from small to large, and were moderate or large in larger samples. However, larger samples of children with and without PPD were related to the largest mean *ds*, as anticipated. Nevertheless, *ESs* in some small studies were possibly underestimating differences between children with and without PPD.

The last study moderator, literacy measure, was tested for differences in construct outcomes from two perspectives on standardization. The first analysis compared evaluations with and without standardization, and the second, specific standardized measures. Non-standardized evaluations were either too small (*DEC*, *SP*) or too various (*PA*) to be split further. With respect to *NWD*, a particular standardized evaluation, the *Woodcock Reading Mastery Test (WRMT)*, [59, 60] was the main test used, leaving no meaningful groupings. However, of the differences between standardized and non-standardized measures for *PA*, *DEC* and *SP*, only *SP* was significant. Large *ESs* were compared on this construct, with the largest ascribed to methods without standardization. This suggested that the types of measures might have been administered differently and/or placed different amounts of emphasis on various orthographic patterns.

Moving to differences among standardized evaluations, comparisons were available for *DEC* and *SP*, with mixed results. In terms of *DEC*, there was no significant difference between measures used within and outside of North America. Conversely, for *SP*, the result was significant between the frequently used *Test of Written Spelling (TWS)*, [90] and a remaining collection of evaluations. In sum, particular standardized tests did not account for significant variability in literacy outcomes; however, when nonstandardized *SP* measures were used, larger differences were found between children with and without PPD.

Overall, literacy outcomes between children with PPD and typical phonology were not significantly influenced by the study design parameters investigated: cultural range, gender balance, sample size or evaluation method. Exceptions to this concerned *SP*, for which differences were related to countries where studies were conducted (i.e., United States versus England), and to whether or not evaluation methods were standardized.

Results for Participant Characteristics

Turning to participant characteristics, Table 3 summarizes the results for the testing of earlier versus later childhood literacy mean ages, PPD severity and resolution, and level of

speech complexity evaluated. Moderators for literacy phase, and PPD characterization were associated with significant differences in *NWD* and *SP* outcomes, while speech complexity had a bearing on all constructs that could be tested, *PA*, *DEC* and *SP*, as outlined below.

Table 3. Participant moderators tested and significance across constructs

Moderator	Groups Tested	PA	DEC	NWD	SP
Range of Mean Age at Literacy ^a	4;0 to 6;11 vs 7;0 to 8;11	✓			
	5;0 to 7;11 vs 8;0 to 10;11		✓	*	*
Resolution	Resolved vs Unresolved	✓	✓	*	*
Severity	Mild & Moderate with/without Severe vs Moderate &/or Severe	✓	✓	*	*
Measures of PPD at Literacy					
Word Lengths	Mono- & Di-syllabic vs Multi- with/without Mono- & Di- syllabic	*	*		*
Speech Context	Single words vs Single words & Connected speech	*	✓		

Note. PA = Phonological Awareness. DEC = Word Decoding. NWD = Nonword Decoding. SP = Spelling. PPD = Protracted Phonological Development. TD = Typical Development.

^a Closest approximation to earlier and later phases of childhood literacy (Chall,1983).

*p < .05

Concerning the first participant moderator, mean age at literacy evaluation, results were significant for *NWD* and *SP* (with adolescent groups removed, e.g., Lewis and Freebairn, 1992 [36]). The test for *SP* also reached homogeneity, suggesting that there was no further variance to explain. Given the caveat of the small sample size for *NWD*, a large *ES* for children in the earlier literacy phase was compared with a negligible mean in the later phase. Negligible means were those obtained from two of the three studies of *NWD* in which children with PPD outperformed those with TD. For *SP* and *PA*, the largest *mean weighted d* was also associated with the earlier phase, but moderate *ds* for *DEC* were virtually equivalent. Notwithstanding the incongruity of negative *ESs* for *NWD*, the results indicated greater differences between children with and without PPD in the earlier phase of literacy attainment, but that the range remained moderate to large.

The next tests of moderators concerned characterization of PPD in terms of severity (combined with subtypes) and resolution. Beginning with severity, studies tended to examine ranges from mild to severe, or from moderate to severe, making tests on more discrete categories unavailable. The comparisons these two groups, however, were significant for *NWD* and *SP* but not *PA* and *DEC*. For *NWD*, the group differences were large and negligible, the latter again because of children with PPD out-performing those with TD. For *SP*, significance related to large *mean weighted ds*, in contrast to nonsignificant moderate *ESs*

for *PA* and *DEC*. An additional comparison for *PA*, i.e., traditional severity categories versus consistency subtypes, also was not significant, between large *ES*s. Therefore, *SP* appeared set apart from the remaining constructs with regard to moderation by severity category.

The third participant moderator tested, resolution of PPD (i.e., resolved or unresolved), yielded a pattern consistent with that of severity: significant for *NWD* and *SP* but without significance for *PA* and *DEC*. For *NWD* and *DEC*, the resolved group was equally split as to full or mixed resolution, but few were of mixed resolution in the tests for *PA* and *SP*. For *NWD*, mean *ES*s between groups that were unresolved and mixed as to resolution, were large and negligible, respectively. Negative *ES*s in the selected studies accounted for the negligible *ES* of the latter group. For *SP*, large *ES*s were compared, the largest in the unresolved group. Nonsignificant group *ES*s for *PA* were also large but for *DEC*, were moderate.

In summary, whether PPD was characterized in terms of traditional severity categories, consistency subtypes or resolution, results were consistently significant for *SP* and *NWD*, with larger effects in groups with the most protracted development. However, *NWD* comparisons were unique in the proportion of negative *mixed weighted ds* attributed to very small samples ($n = 3$). In contrast, moderate to large nonsignificant differences for *PA* and *DEC* were maintained between children with PPD and TD.

The last participant moderator regarding characterization of PPD was complexity of speech evaluation context. For this moderator, two tests were possible: single words versus single words combined with connected speech, and in terms of word length by syllables, monosyllabic combined with disyllabic words versus MSWs whether or not combined with mono- and disyllabic words. *PA* and *DEC* were tested with regard to connected speech evaluation, which in the studies was always supplemented with single word assessment. Results were contradictory, with significance for *PA* but not *DEC*. For *PA*, the *ES*s compared were large and moderate, and for *DEC*, both moderate. However, in both cases, the larger mean was ascribed to single word evaluation, suggesting that word complexity as opposed to connected speech, was the more relevant context to word level literacy.

Concerning word length differences, *PA*, *DEC* and *SP* were tested, and all results were significant. *PA* was the only construct for which MSW evaluation could be compared in isolation of shorter words. For this comparison, the difference between large and moderate mean *ES*s was homogeneous, suggesting that the moderator of word length accounted for all of the variance. The tests for *DEC* and *SP* compared moderate and large mean *ES*s, respectively, with the largest effects for studies that included MSW evaluation, whether or not in combination with shorter words. These results also implied that word complexity was a relevant factor in literacy differences.

In summary, the overarching findings of the tests of participant characteristic moderators were threefold. First, the mean *mixed weighted ds* for subgroups remained moderate to large between children with and without PPD on all constructs except *NWD*. This construct, with the smallest sample size, showed an anomalous association with negative *ES*s, suggesting greater caution about the related findings. Second, characterization of PPD in terms of literacy acquisition phase, or severity, as determined by traditional categories (with subtypes included) or resolution, was significant for *NWD* and *SP*, but not *PA* and *DEC*. Irrespective of significance, larger *ES*s were consistently found in groups with the most protracted phonological development. Third, for constructs tested on complexity of speech evaluation context, *PA*, *DEC* and *SP*, results were significant when MSWs were assessed, whether or not in conjunction with shorter words. A significant result for *PA* when connected speech was

combined with single word evaluation, also suggested that the evaluation of short single words alone is insufficient for characterizing the phonology of school-aged children.

DISCUSSION

A meta-analysis was conducted to evaluate contradictory findings in the literature concerning the relationship of protracted phonological development and literacy acquisition. [6, 8, 24] Clarifying the basis for such differences might inform the design of therapies for spoken phonology in the future, which in turn might enhance literacy outcomes. The meta-analysis set out to determine the convergence of evidence about the magnitude of literacy differences, and the moderating effects of central study and participant characteristics.

The meta-analysis examined two possible major sources of variation in literacy outcomes between studies: (1) evaluation of specific word level literacy constructs of *Phonological Awareness (PA)*, *Decoding (DEC)*, *Fluency (FL)*, *Nonword Decoding (NWD)* and *Spelling (SP)*, and (2) participant characteristics regarding age at literacy evaluation and/or characterization of PPD. The ensuing research questions asked whether differences: (a) were consistent across constructs; (b) varied by age in terms of the stage of childhood literacy (earlier, *learning to read*, versus later, *reading to learn*); and (c) varied depending on researchers' characterization of PPD, as defined by severity/subtype, resolution, or the complexity of speech elicitation context (i.e., word length by syllables, or single words versus connected speech). Before answering these questions about participant characteristics, it was necessary to assess whether aspects of study design also explained variance in literacy outcomes; consequently, moderators of cultural context, sample size, gender and specific literacy measures were tested.

Review of Key Methodology for the Meta-Analysis

In the next section, the methodology for the meta-analysis is reviewed as a qualifying context for the discussion of descriptive and inferential results that follows.

A descriptive analysis addressed the first question of the study: Are children with PPD consistently disadvantaged in word level literacy acquisition compared with TD peers, and if so, to what extent? Initially, *effect sizes (ESs)* for the mean differences between children with and without PPD (*unbiased Cohen's d*) were calculated for 67 independent samples identified in the 34 included studies. Distributed across the literacy constructs, sample sizes were as follows: *PA* ($n = 20$), *DEC* ($n = 17$), *FL* ($n = 4$), *NWD* ($n = 9$), and *SP* ($n = 14$). The *ESs* corresponding to all constructs were predicted to be moderate to large, with the largest expected for *SP*. Outliers were inspected visually in funnel plots. To treat the identified outliers, all *ESs* were weighted by two factors: (a) the *inverse variance*, to adjust study influence by sample size, and (b) the *Random Effects Variance Component (REVC)*, because the included studies were likely estimating for different populations of studies. Then, by constructing forest plots of the *95% Confidence Intervals (CIs)* and the *95% Credibility Intervals (Cred Ints)*, the significance and generalization of *ESs* were examined. The significance of study differences was judged in relation to the *CI* for the construct mean,

which also suggested generalization to the population for the sample of included studies. More stringently, the corresponding *Cred Ints* indicated whether the construct mean was representative of all possible populations of studies, completing the descriptive analysis.

An inferential analysis was subsequently conducted to address the primary research questions about participant characteristics. Initially, multiple regression analysis (MRA) was used to establish that there was sufficient variance among the *ESs* on any construct, to test the moderators. The conflicting literacy outcomes identified in the research suggested that all variances would be significant, predictions confirmed by the MRA ($p < .05$). This allowed the moderators of age at literacy measurement and characterization of PPD to be evaluated on the *Q* statistic (similar to *Chi-square* for categorical variables) whenever constructs had sufficient studies to group on these variables. Following from this requirement, *FL* was excluded from the moderator analyses because of its small sample size.

Before assessing the moderators for the research questions, the study design moderators were tested. Significance was considered possible for cultural context, gender, and specific literacy measures, but less likely for sample size. In terms of cultural context, potential significance related to the range of countries where studies were conducted. Second, concerning gender ratio, a major imbalance was expected to significantly bias *ES* magnitudes in favour of girls. Third, regarding specific literacy measures, moderation could arise from the psychometric rigor of standardized as opposed to non-standardized measures. Further to standardized measures, any differences were predicted to relate to cultural contexts. Finally, with respect to the wide sample size ranges across studies, and between groups with and without PPD, it was expected that the weighting of the *ESs* would be an adequate adjustment.

Following the testing of the study design characteristics, participant characteristics were evaluated in the inferential analysis. Concerning the first of these, age at literacy measurement, it was anticipated that differences between children with and without PPD would have widened by the later childhood literacy phase. Second, the various methods for defining PPD, whether in terms of severity, subtypes or resolution, were all predicted to be significant for two reasons. First, assuming the connection between spoken phonology and word level literacy, [18, 19] more protracted phonological development could reasonably be expected to slow literacy acquisition. Second, it was possible that severity, subtypes and resolution essentially described equivalent constructs of PPD. Last, regarding speech elicitation context, significance was expected because of the added length and complexity of word structure and phoneme sequences in multisyllabic words or connected speech.

Effect Size Results

The first question for the meta-analysis concerned whether differences in word-level literacy skills, between children with and without PPD were consistent. As predicted, uniformity, was demonstrated by moderate to large mean *ESs* between children with and without PPD, for all examined constructs: *PA*, *DEC*, *FL*, *NWD* and *SP*. However, in the examination of outliers, negative *ESs* were unexpectedly identified, indicating that children with PPD had outperformed their typically developing peers. This circumstance bears discussion before further considering the magnitude of the *ESs* overall.

There were two important statistical observations about negative *ESs*: (a) magnitudes were typically negligible, [24, 47] and (b) all were without significance because their

confidence intervals contained zero. The magnitudes therefore caused little impact on the mean *ES* for a given construct and were not generalizable beyond the primary study. Explanations for the negative direction might relate to several aspects of meta-analytic and primary research methodologies, depending on the construct evaluated. Concerning *PA*, for selected sub-groups with PPD, provision of *PA* intervention [47] could have enhanced performance on dependent *PA* variables. With respect to *DEC*, *FL* and *NWD*, the meta-analytic calculation of *ESs* from participants' gain on selected data often resulted in a negative value. Consideration of these data, however, showed gain from below average to average-range scores for children with PPD, but from two average range scores for children with typically developing phonology. In some studies, [2, 24, 25] both groups of children lost ground across measurement points, but children with PPD fell behind to a lesser extent. From these observations, it appeared that children with PPD had lower literacy at the outset, and as such, had less to lose.

There were also sample and construct biases in primary studies, unanalyzed in the meta-analytic process, but which may have contributed to negative *ES* findings. Sample bias was probable in terms of: (a) heterogeneous samples stemming from wide age ranges, [36, 64] and (b) children with PPD having higher performance than comparison groups on constructs highly correlated with literacy, e.g., verbal language comprehension and/or production, or nonverbal IQ. [68] Construct validity was relevant to samples that showed equivalent *DEC* and *NWD* attainment in earlier childhood literacy, but that later demonstrated moderate differences in comprehension. [14, 38]

Having considered the influence of negative *ES* outliers, the discussion next deliberates the moderate to large mean *ESs* between children with and without PPD. Such magnitudes were borne out for all constructs examined in word-level literacy; nevertheless, construct-specific magnitudes were not altogether as expected. First, the largest differences were predicted for *SP* (*mixed weighted d* = .84) because it was theoretically the most complex skill of the included constructs. However, means were also large for *PA* (*mixed weighted d* = .85) and *FL* (*mixed weighted d* = 3.04). Next, finding moderate *ESs* for both *DEC* (*mixed weighted d* = .60) and *NWD* (*mixed weighted d* = .50) was unanticipated because of suppositions that *NWD* reflects automaticity of sound-symbol relationships. Overall, the *ES* findings suggested that as a group, children with PPD could be expected to score about one standard deviation below peers with TD in *PA* and *SP*, and up to three standard deviations lower in *FL*. For *DEC* and *NWD*, performance of children with PPD appeared approximately one-half of a standard deviation below those with typically developing phonology. Because most studies accounted for SES factors and nonverbal intelligence, the *ESs* derived from the meta-analysis suggested that children with PPD were consistently underachieving in literacy. These differences apparently held *even when children classified as having mild, moderate and severe PPD were examined together (due to inability to isolate sufficient sub-samples in the included studies)*.

From a theoretical perspective, explanations for the magnitude of *ESs* found in the current meta-analysis might relate to accessing of phonological and orthographic (i.e., letters) representations. Both types of knowledge are likely utilized to varying degrees from the earliest stages of reading and spelling, [81] with reciprocal influences. [82] Other researchers who shared this perspective, [50, 83, 84, 85, 86] considered phonological representation to be a necessary but insufficient foundation for word decoding. Lehtonen (2009) [82] also argued that beginning knowledge of the relationship of phonemes to alphabetic orthography is

required for word-level literacy to emerge. Evidence of other early orthographic knowledge comes from Apel, Wolter and Masterson (2006) [87]. These researchers reported that orthographic processing explained unique variance in young children's spelling detection and written output of novel words, given only minimal exposure to their forms in print. With respect to later literacy, Duncan (2009) [41] defended the notion of ongoing development of phonological and orthographic representations needed to read and spell complex words.

In terms of *ESs* specific to the included literacy constructs, interactions between phonological and orthographic representations that are likely complex lead to relative dependencies that are not uniform. Presumably, speech production is strongly connected to phonological representations that are involved in reading and spelling. Therefore, in tasks of *PA*, primary reliance on phonological organization up until *cracking the code* of print, could account for the large difference between children with and without PPD. As the ability to decode words progresses, reciprocal contributions of the phonological and orthographic systems advance *PA* ability. However, children with history of PPD might continue to be disadvantaged. For example, children might experience confusion over less transparent sound-symbol correspondences, i.e., letters or letter patterns that are associated with more than one speech sound, and the converse, where a single speech sound relates to more than one letter pattern. In another case, children might have difficulty understanding the relationship of a base word to related morphologically complex words. [1]

Mutual dependence on phonological and orthographic representations is more probable for *DEC*, *FL*, *NWD* and *SP*, from the outset of their development. Between children with and without PPD, the large *ESs* for *FL* and *SP* could logically be precipitated by the added factor of skill automaticity. Automaticity is required for success in *FL* by definition, [10] but also is relevant to *SP*, [49] because of the overlay of writing the orthography (i.e., insofar as the evaluation methods used in the included studies). Less demand for automaticity could be attributed to the moderate *ESs* pertaining to *DEC* and *NWD*. In both of these processes, speed of connections between phonological and orthographic systems are likely determined by accessing phonological components of assorted sizes, including those related to lexical frequency and neighborhoods, e.g., onset and rime patterns. [41, 82] The lexical restructuring theory suggests that stronger connections to lexical information would facilitate accuracy of *DEC* over *NWD*, [19, 44] in the same way that vocabulary growth is proposed to create ongoing refinement of the spoken phonological system. [88, 89]

A final point of discussion about the mean *ESs* for the literacy constructs concerns generalization. The 95% *CI*s were significant for all but *FL*, suggesting that the results for *PA*, *DEC*, *NWD* and *SP* were generalizable to other samples of studies described by equivalent moderators. As noted earlier, the very small sample of studies of *FL* ($n = 4$) and the unique large database sample ($n = 10,221$) studied by Puranik et al. (2008), [10] made it difficult to draw further conclusions beyond the current included studies. However, the large *ES* calculated from the *FL* data selected for the meta-analysis predicted that *ESs* of similar magnitude could also be expected given similar database samples and *FL* measures. In terms of generalization to populations of studies described by other moderators, only the 95% *CredInt* for *PA* was significant, perhaps owing to the breadth of tasks tested that made up the composite scores. The discussion now turns to the assessment of moderators included in the current meta-analysis, first with regard to study characteristics, and then participant characteristics of direct relevance to the remaining research questions.

Study Characteristic Moderators

To explain *ES* differences between children with and without PPD, the literacy outcomes were tested for study moderator influence before addressing the participant characteristics for the main research questions. With the exception of *NWD*, all constructs were tested on cultural context, sample size, gender, and specific literacy measures. *NWD* was excluded from testing on the latter two grouping variables because there were no meaningful splits available. An overall assessment of the results for the study characteristics suggested that effects were not even. However, certain patterns surfaced, including that: (a) gender ratio was primarily not a moderator, (b) sample size was a moderator for several constructs and, (c) effects were more frequent for *SP* than for any other construct. From this general assessment, a more in-depth discussion of the study characteristics selected for the current meta-analysis will first consider cultural context and measure used because of their associations with *SP*, followed by gender and sample size effects.

Concerning *SP*, cultural context and standardization of measures were significant moderators specific to this construct. Cultural context differences were pertinent to the two countries in which the majority of studies took place, the United States and England, but appeared unrelated to differences in particular standardized evaluations. Sub-groups of specific standardized measures compared a more recently published test, the *Test of Written Spelling* (*TWS*), [80] with older publications used outside of the United States, e.g., the *Schonell Graded Word Spelling Test*, 1956, [90] and the *Graded Spelling Test*, 1977, [91] also without effect. Therefore, other explanations for cultural differences were considered with regard to spoken English dialect.

Researchers have suggested that it could be useful to confirm whether or not dialect influences skills related to word-level literacy, e.g., morphological awareness. [1] From the perspective of the included studies, differences in American and British spoken English dialects might account for the observed effect of cultural context on *SP*. That is, with regard to sonorous segments (vowels or consonants with spontaneous voicing), spelling challenges might vary because of different pronunciations represented by the same orthography. For example, using tasks of phoneme identification in CVCC and CCVC spellings, Lehtonen (2009) [82] has demonstrated the influence of sonority on *SP*. When sonorant consonants (e.g., *r* and *l*) appeared in consonant clusters in the words (e.g., *pl*, *br*, *rk*, *lk*), both child and adult speakers of American English more often chunked the consonant with the preceding or following vowel. How speakers of American and British English might treat the same contexts would be of interest, because the dialects contrast as to whether spelled sonorant consonants are pronounced, e.g., *r* or syllabic *l*, in words such as *water* or *bottle*, respectively. School instructional practices in *SP* might also vary accordingly.

Another study characteristic concerning *SP* was the significant effect of non-standardized evaluations, which differed from traditional standard tests that have basal and ceiling effects. For example, Nathan et al. (2004) [32] analyzed the results of British Statutory Assessment Tests that evaluated the spelling of 30 words not normally used in the children's written compositions. Words included both monosyllables and MSWs with and without regular orthographic patterns. Based on whole word scores, children were assigned to one of three academic attainment levels expected for grade in school. However, some studies used methods other than whole word scoring, accounting for spelling of smaller word elements. Snowling and Stackhouse (1983) [31] asked four children identified with *Childhood Apraxia*

of Speech to spell 52 familiar CVC words comprised of stop and nasal consonants (i.e., *m*, *b*, *p*, *t*, *d*, *n*, *g* and *k*). Consonant spelling was studied in relation to change across three places of articulation; therefore, vowel spelling was not considered. Apel and Lawrence (2011) [1] scored phonemes and morphemes on a 15-word dictation test. In the latter two studies, relatively large samples of children with and without PPD were examined (i.e., $n = 74$ and $n = 88$, respectively), with significant *ESs*. For the group of studies, the significant difference was between large *mean ESs*, but was larger when non-standardized measurement was used. Rather than applying basals and ceilings, it appeared preferable to have children spell a representative sample of word structure and orthographic components [1], thereby gaining a more specific analysis of spelling abilities.

The study characteristic concerning gender ratio, was tested independently in groups with and without PPD for *PA*, *DEC* and *SP*, and for *NWD*, in the group with PPD. Gender ratio in the group with TD was a moderator for *PA*, but was without significance in any of the other tests. Normative information about childhood phoneme acquisition has sometimes suggested gender differences, [79] but whenever reported, has favoured girls. [91] Therefore, in relation to children with PPD, an effect due to higher male proportions in the group with TD would predictably reduce *ES* differences, a prediction upheld for *PA*. However, other available normative data that have not indicated gender distinctions, [77, 78] were aligned with the nonsignificance of gender ratio in the studies overall.

Sample size was also independently evaluated in groups with and without PPD for all constructs. Sample sizes were often between non-equivalent groups, the largest mainly ascribed to children with TD, [7, 39, 67] because recruiting large samples of participants with PPD is frequently difficult. In the tests of the sample size moderator, only two tests were not significant: children with PPD in studies of *PA*, and those with TD in studies of *DEC*. In the significant comparisons, the largest *mean ES* was attributed to the group of studies with larger samples. Therefore, it is possible that *ESs* were underestimated in the studies with smaller samples of either group of children.

Participant Characteristic Moderators

The discussion moves on to the moderators of central interest in the current meta-analysis, the participant characteristics. These were defined in terms of phase at literacy evaluation, i.e., early (*learning to read*) and later childhood (*reading to learn*), plus parameters characterizing PPD, i.e., severity/sub-types, resolution and complexity of speech context evaluated. In the following section, the results for the tests of each moderator will be discussed in turn and conclude with the support they lend to theoretical views about the course of literacy acquisition for children with PPD.

Regarding age range or phase of literacy development, synopses in the literature offered mixed conclusions about whether there are persistent differences in the literacy of children with and without PPD. [1, 8, 10, 11, 36] The current meta-analysis suggested ongoing large or moderate differences in *PA*, *DEC* and *SP*, but not in *NWD*. Also relevant to these differences was whether magnitudes were smaller in the later childhood phase, and any variation in results among the constructs. For *PA* and *DEC*, moderate differences were maintained but in *SP*, differences declined from large to moderate in the later age groups. The *ES* for *NWD* also decreased, from large to negligible, an unexpected finding given that

performance of this skill theoretically is highly dependent on the phonological to orthographic relationships of literacy. This unique outcome for *NWD* in the later childhood literacy phase must be considered with caution however. Specifically, the *mean mixed weighted d* was obtained from small samples of children ($n = 100$) and studies ($n = 3$), and in two of these, children with PPD outperformed those with TD. Nevertheless, if the difference in *NWD* between children with and without PPD does close by the later phase of childhood literacy, the gain might in turn explain the magnitudes of difference for the other literacy constructs. Researchers have been of the opinion that proficient *NWD* will enable fluent word decoding, [10] and spelling, [49] with reciprocal effects on phonological awareness. [1] Stronger phoneme-to-grapheme correspondences demonstrated in *NWD* should in turn spill over to *SP*. [41] Thus, *SP* proficiency might align with *PA* and *DEC* abilities, as was the case in the current tests of the moderator (i.e., all three constructs with moderate *ESs* in the later phase of childhood literacy). Facility with *NWD* might also have been sufficient to prevent *PA* and *DEC* differences from increasing, enabling some children with PPD to attain word-level literacy in the average range.

Characterization of PPD was also determined to be relevant. The first characteristic examined was the children's status in terms of resolution of PPD. Coding on this parameter generated studies of children whose PPD was unresolved, resolved or mixed (a combination of both). In order to avoid confounding the group of studies of unresolved PPD, studies of mixed samples were added to those that examined children with resolved PPD exclusively. This strategy potentially reduced the *ES* for the group mixed as to resolution of PPD. However, for each literacy construct, the proportion of resolved PPD in the sub-group was always greater (range = 0.67 to 0.80), with relative increases in the mean *ES*. This circumstance helped to minimize the confound.

The tests of the resolution moderator resembled those for age range in two respects: (a) the magnitudes of the sub-group mean *ESs*, and (b) the significance of results. For *PA* and *SP*, the mean *ESs* were large, and for *DEC* were moderate, whereas large and negligible *ESs* were tested for *NWD*. Results were significant for *SP* and *NWD*, but not for *PA* and *DEC*. Whether or not significant, differences between children with PPD and TD were not confined to groups of children with solely unresolved PPD. The results for *NWD* were again exceptional, suggesting that children with resolved PPD history did not differ from children with TD. However, as described above, the small sample of studies of *NWD*, including those in which children with PPD outperformed those with TD, suggested caution in interpreting this outcome.

The differing results among the literacy constructs on the tests of resolution were possibly related to the numerous methods that determined status of PPD, used singly and in combinations. Frequently, percent consonants and/or vowels correct (PCC/PVC) were determined for published elicited single word tests or conversational samples. Criterion-referenced cut-offs were established for these measures in terms of percentile rank, standard score, number of phonological processes, or percentage of whole word production inconsistency. Puranik et al. (2008) [10] also described various Florida Department of Education therapy eligibility criteria that referred to either: number and years of delayed consonants in relation to normative acquisition data, intelligibility judgment, disordered error patterns, or rating of moderate to severe impairment on an articulation rating scale. Nevertheless, the similarity of results for the tests of resolution compared with age at literacy measurement, suggested that both moderators indexed growth in phonology and literacy.

Puranik et al. (2008) [10] presented such a trajectory for children with PPD in terms of *FL*, from Grade 1 through Grade 3, with marginal differences indicated between children with persistent as opposed to resolved PPD.

Severity or sub-type categories relative to characterization of PPD were tested in two ways: by comparing traditional severity categories with inconsistency sub-types, and by comparing rankings within severity categories. Sufficient studies existed for testing the inconsistency subtypes only for *PA*, with nonsignificant results. Although limited to *PA*, this outcome supported the validity of combining the subtypes with the traditional severity categories, affording a larger sample size for the second comparison. Within severity categories, tests of moderate to severe and mild PPD were conducted. The magnitudes of subgroup *ESs* for each construct replicated those used in the tests of mean age and resolution, in addition to iterating the patterns of significance, i.e., significant results for *NWD* and *SP* but nonsignificant for *PA* and *DEC*. For all literacy constructs, the analogous results for resolution and severity/subtype categories suggested that the moderators defined equivalent constructs of PPD, and represented the course of the children's phonological development. For some children not identified with PPD until the early phase in which literacy was also evaluated, severity/subtype and resolution coincided. Where children were identified prior to the later phase in which literacy was measured, severity/subtype and resolution measured status of PPD at different points on the continuum.

Specific evaluation methods were also relevant to characterization of PPD. The results of the meta-analysis suggested that a more useful option for understanding the relationships between PPD and literacy was to use continuous rather than categorical levels of measurement, as argued by Peterson et al. (2008). [8] In the current meta-analysis, the appropriate complexity of speech context for obtaining such levels of measurement was tested in terms of evaluation of connected speech and of multisyllabic words in the phonological assessments. Researchers have contended that proficiency of spoken MSWs is relevant to whether PPD is resolved, and in turn, to literacy outcomes, and so MSW evaluation was predicted to be a significant moderator. [3, 9, 36, 37, 47, 53, 58] In comparison with mono- and disyllabic single word elicitation, the additional complexity of spoken phonology in connected speech was also expected to significantly moderate literacy differences. The only construct that could not be tested on the speech complexity moderators was *NWD*, but comparisons on the remaining constructs suggested that context made a difference. Specifically, on the moderator of word length, results were significant for *PA*, *DEC* and *SP* and the connected speech moderator was also significant for *PA*. The significance of these moderators, which differed from the outcomes of resolution and severity/sub-types, might concern sampling of children in the various studies. Children whose phonology had not been assessed in more complex phonological contexts might have been assigned to categories of resolved or less severe PPD, or possibly excluded from studies altogether.

Further to evaluation of word length, MSWs was an important factor, with significant effects on all of the tested constructs, *PA*, *DEC* and *SP*. Results were significant when evaluation of mono- and disyllabic words was compared with assessment of MSWs with or without mono- and disyllabic words. These findings suggested that the addition of MSWs provided supplemental information about the children's phonological development. For *PA*, the effect of MSW evaluation was further highlighted when studies that had amalgamated mono-, di- and multisyllabic words were removed, resulting in a significant homogeneous comparison of mono- and di-syllables with MSWs. Regarding *ES* magnitudes, the studies that

evaluated MSWs showed a large difference between children with and without PPD, whereas the difference was moderate for studies that assessed principally mono- and di-syllables. With respect to *DEC*, moderate *ESs* were tested and for *SP*, *ESs* were large, as opposed to moderate, when more MSWs were evaluated.

The final examination of speech context compared studies that only evaluated single words versus those that combined single words with connected speech. This was considered a valid comparison because assessment of phonology in connected speech generally entails also examining single word elicitations. [34] Of the literacy constructs, only *PA* and *DEC* could be tested on the moderator of connected speech assessment, with *PA* significant and *DEC* not. Concerning *PA*, the magnitudes of the *ESs* in the significant comparison for single words were larger than were tested in the combination of single words and connected speech. In contrast to predictions, this finding suggested that the general structure of words in connected speech might have been simpler than that of elicitation corpora. This is consistent with Shriberg and Morrison (1992), [33] who reported that in comparison with word-elicitation tests, words in conversational samples were simpler in structure, and included a relatively lower proportion of multisyllabic words.

In summary, for the participant characteristics, three patterns were identified. First, *NWD* and *SP* were moderated by all of the participant characteristics, whereas only the evaluation method for PPD had effects on *PA* and *DEC*. These results support suggestions that *NWD* and *SP* are more sensitive to the strength of, or access to underlying phonological representations, possibly because of heavier reliance on systematic connections between phonological and orthographic representations. [49, 55] A second pattern was the significance of PPD assessment methods for all constructs tested, i.e., *PA*, *DEC* and *SP*. Phonological evaluation methods appear to be a crucial variable for differentiating literacy performance of children with and without PPD, and are relevant to a continuous scale of measurement, [8] as opposed to categorization by severity/sub-type or resolution. The third pattern concerned specific contexts of phonological assessment, particularly MSW evaluation. Studies that included these complex phonological contexts during assessment, showed more systematic relationships with literacy acquisition. This has clinical implications, as discussed below in the conclusions.

Theoretical Views about Lower Literacy in Children with PPD

Both uni- and multi-dimensional interpretations have appeared in the literature to explain the relationship of PPD and lower literacy skills. Uni-dimensional explanations refer either to an underlying cognitive process or to the developmental timeline of child phonology. A cognitive view is that a *core phonological deficit* contributes to poor phonological representations that slow down the acquisition of literacy skills. [85] In terms of the pace of phonological development, supporters of *the critical age hypothesis*, [32] suggest that the impact of PPD on literacy is mitigated significantly by resolution prior to formal literacy instruction. Other recent perspectives have favored the interaction of multiple components in word-level literacy, in terms of: (a) multiple linguistic and nonverbal cognitive deficits, [8, 11] (b) synergies between language-based skills, [36] and (c) overlaps of multiple levels of linguistic awareness, including phonemic, morpho-syntactic and orthographic components. [1, 5] Because the moderating effects of the participant characteristics were various, the

current meta-analysis substantiates a version of multiple component interaction for explaining the relationship between PPD and word-level literacy acquisition. To the contrary, consistently significant moderating effects on all of the literacy constructs would have supported a core deficit in phonological representations in children with PPD. Alternatively, no effects in the later literacy phase, nor in terms of reduced severity or resolution, would have defended a critical age by which phonology must be *normalized*. Conceptions about the interaction of multiple linguistic components are more convincing in terms of both current language processing models, [92] and nonlinear linguistic theories of spoken phonology. [27] These explanations were also more consistent with the significant effects of speech production context, particularly with regard to the complexity of MSWs.

CONCLUSION

The current meta-analysis was the first to systematically examine the relationship of PPD and literacy. Moderate to large differences were found between children with and without PPD on all of the word level literacy constructs, and were larger in the earlier than in the later childhood literacy phase. Cultural context (United States versus England) was a moderator of *SP*, likely as a result of differences in English dialect. Among the moderators characterizing PPD, all were significant for *NWD* and *SP*, whereas only evaluation method had effects on *PA* and *DEC*. The assessment of phonology in complex linguistic contexts moderated all literacy constructs tested (*PA*, *DEC* and *SP*), mainly regarding evaluation of MSWs, but assessment of phonology in connected speech was also significant for *PA*.

The meta-analysis was limited by the restricted number of studies that could be included, and the small samples generated for each of the literacy constructs (*PA*, *DEC*, *FL*, *NWD* and *SP*), especially for *FL* and *NWD*. Fewer than 25 samples were identified for any of the examined constructs, and fewer than 10 for *NWD* and *FL*. The findings for *PA* were likely the most robust because of the larger sample of studies. The large differences for *FL* between children with and without PPD were not significant, and the small number of studies excluded this construct from the moderator analyses. However, differences for other constructs were significant, and hence generalizable to the population of the included studies (large differences for *PA* and *SP*, and moderate differences for *DEC* and *NWD*). The differences for *PA*, *NWD* and *SP* were also generalizable to other possible populations of studies. In the future, additional studies of all chosen literacy constructs are needed, particularly of *NWD* and *FL*. More studies could enhance generalizability of findings through a replication of the meta-analysis that evaluates all constructs on all chosen moderators.

Another limitation relative to the restricted set of studies was the number of moderators tested, done in order to reduce the possibility of Type I errors in the significant *Q*-tests. Testing additional moderators in the future might help account for the heterogeneity within sub-groups, particularly because few tests of the moderators had a homogeneous result. Homogeneity was limited to mean age at literacy evaluation for *PA*, and for *SP*, gender in the PPD group, and characterization of PPD in terms of word length. Because it is difficult to isolate generally protracted language development in the characterization of PPD, in future research, evaluating language development as a moderator could inform the relative effects of language and phonology on literacy [8, 36]. Testing narrower age ranges may uncover more

incremental differences in literacy acquisition. For example, for *FL*, Puranik et al. (2008) [10] showed developmental trajectories in age levels from one school grade to another, using growth curve modelling.

Methodologies in the studies included also limit the impact of the meta-analysis. There were, overall, relatively low numbers of children with PPD in the selected studies. Researchers have commonly commented on the challenge of acquiring large enough samples with power to detect differences between children with and without PPD. Within the included studies, two-thirds sampled fewer than 25 children in either of the comparison groups and in the remaining one-third, rarely more than 100 children comprised either group. To address the issue of sample size, investigators have recently turned to secondary data from databases, for retrospective study designs. [7, 10] To design larger prospective studies, primary data might also be retrieved (e.g., from CHILDES). [93] A caution about these alternate methodologies is the inability to ensure equivalence of procedures for selecting participants and gathering data. Therefore, comparing findings from database samples to those in primary studies would be a valuable future endeavour.

Another issue regarding sampling methodology in the selected studies concerns participant characteristics. For the current meta-analysis, studies had insufficient groups of children with moderate to severe PPD, confirming that more studies are needed concerning the literacy of these children. [30] To increase the validity of categorical characterization of PPD and the ability to compare research results, researchers may need to standardize the evaluations and criteria for sub-group assignment. Alternatively, according to researchers such as Peterson et al. (2009), [8] relationships between PPD and literacy could be evaluated on a continuous scale. In this way, power can also be addressed, while avoiding semantic confusion of category labels and the arbitrary nature of participant assignment. Continuous scales could be incorporated in longitudinal designs to better follow the course of PPD and draw conclusions about the strength and direction of the relationships to literacy. Longitudinal designs might further include children with history of PPD whose early childhood literacy seems satisfactory, but whose later literacy is compromised in some way, especially in reading comprehension and written composition. [94]

Another important consideration for evaluating PPD status in future studies, also relevant to clinical practice, is the assessment of competence in complex linguistic contexts, the next topic of discussion. Evaluation of linguistic complexity pertains not only to phonological production in connected speech, [8, 12] but also in multisyllabic words. [35, 36, 38] However, there is no theoretically sound norm-referenced multisyllabic word evaluation method that is easily replicable for single word and connected speech elicitation. In research, words tested have varied, [9, 37, 53] and in some cases, variability of whole word production has been evaluated. [47, 58] Creation of a valid MSW corpus necessarily will entail inclusion of representative word structure and consonant sequences, consideration of word familiarity in terms of cultural and academic contexts, and imageability.

The connection between spoken MSW production and literacy demonstrated by the meta-analysis is of clinical relevance in terms of planning intervention for children with PPD. Researchers in literacy have stressed the need for ongoing elaboration of the underlying structure that supports reading and spelling more complex words. [41] This implies that information gained from parallel evaluations of speaking, phonological awareness, reading and writing of MSWs might allow speech-language pathologists to better tailor therapy programs. For example, beyond whole word scoring, more detailed rubrics have been applied

to children's spellings, in order to account for the phonological components of words that have not been represented orthographically. [64] Even without benefit of comparable measures for other word-level literacy constructs (i.e., *PA*, *DEC*, *FL*, and *NWD*), MSWs selected for speech therapy could also be practiced in meaningful word-level literacy to reinforce connections between phonological, orthographic and semantic components.

A final clinical implication of the meta-analysis is the additional support for early intervention. Larger differences between children with and without PPD were observed in the early childhood as opposed to later childhood literacy phase. Potentially, earlier therapy that contributes to progress in the first phase would catalyze further reduction of later differences. Increases in children's performance in *PA* to average or better levels following early intervention, [5] suggest that similar effects are possible for other word-level literacy constructs.

The studies examined here enabled the current meta-analysis by contributing a body of data concerning the relationship of PPD to word-level literacy. The meta-analysis confirmed that children with PPD are at risk for literacy development. The findings underline the importance of evaluating PPD in complex linguistic contexts, in order not to miss children who appear to have mastered the basics of spoken phonology but continue to be challenged by greater complexity. Future meta-analyses of larger samples of studies are needed that relate literacy attainment to PPD measured on a continuous metric, and that also examine outcomes of different phonological and literacy interventions in the preschool and early school years.

ACKNOWLEDGMENTS

The authors would like to thank Sarah Blois for completing the coding for reliability, and Dr. Nand Kishor for clarification of meta-analysis procedures. The authors would also like to thank Dr. Jeff A. Small and Dr. Julie J. Masterson for supporting the project as part of the first author's doctoral work. Finally, thanks are extended to Valerie Marshall for valuable assistance with formatting.

Chapter 28

CLINICAL OUTCOMES IN MEDICAL SPEECH-LANGUAGE PATHOLOGY

***Richard M. Merson*, PhD, CCC-SLP
and Michael I. Rolnick, PhD, CCC-SLP***

Department of Speech & Language Pathology.
Beaumont Health System, Royal Oak, MI

ABSTRACT

This chapter will report on a large patient population (est. 20,000 from 1992-2013) from the Beaumont Health System (Michigan) which had been tracked consecutively on two different clinical outcome programs since 1992. The population includes inpatients and outpatients treated at multiple hospital and rehabilitation centers. Adults and children with communication disorders were tracked utilizing a customized clinical outcome software program (The Beaumont Outcome Software System ©, BOSS) with a large clinician based staff. After ten years the Speech-Language Pathology Department, Beaumont Health System transferred their outcome program to the American Speech-Language Hearing Association's National Outcome Measurement System ©, NOMS). This chapter reports and compares the two clinical outcome systems (BOSS© and NOMS©) and discusses how outcome data contributes to Speech-Language Pathology management.

Keywords: speech, language, outcome, pathology

PURPOSE AND VALUE OF CLINICAL OUTCOMES

There are many forms of clinical measurement. [1, 2, 3] The scientific development of standardized testing is a long and rigorous process that may include instrumental or psychosocial assessment. Normative standards of disease and management in clinical

* Corresponding Author Email: rickmerson@beaumont.edu.

medicine and rehabilitation are abundant and utilized by clinicians, researchers and academics. These highly sensitive objective measures assist the professional in differential diagnosis, assessing impairment severity and making predictions for future quality of life considerations.[3] Clinical outcomes, however, are functional measures of change overtime on a standardized subjective clinical scale among individuals with a common diagnosis. [2, 4, 5, 6] They are not indications of diagnosis, impairment, absolute performance, competence or capacity. They are poor predictors of the future quality of life or final achievement of rehabilitation potential. They are expressions of progress. They are not highly sensitive, precise measures of overall clinical competence. Nor do they predict permanence. Clinical outcomes can describe the effectiveness of the treatment strategy implemented to improve the patient's status during the time measured. They may be correlated to costs, can be used to compare clinician performance, program types, and analyze patient demographics. They are at the least, a poor predictor of the final possible outcome and at the most an indication of the effectiveness of the treatment intervention at the time. They are a measure of movement, much like a thermostat, that tells nothing about the source, or the future of temperature change, just that there is more or less heat. Outcomes are not like a complex computer program differentially diagnosing diseases, or proposing strategies for treatment programs. Outcomes can tell you there is change and it's moving in the right direction. This is in fact what our payors, administrators, politicians, and patients want to know from our clinical interventions. Center for Medicare-Medicaid System (CMS) does not necessarily want to know the exact outcome or exact achievement but rather the effectiveness of a treatment program to produce progress. [7] That's what they will pay for, and that is what we can describe as "clinical value". Payors, patients and politicians know that the actual outcome is highly dependent on a large series of variables dependent on the individual and environ. They want to pay for progress, and they want a report card compared (benchmarked) with other providers. [6]

BEAUMONT OUTCOME SOFTWARE SYSTEM© 1995

In the early 1990's William Beaumont Hospital, a 1000 bed multiple hospital and rehabilitation center system decided to take clinical outcomes seriously. Their major departments were encouraged to seek out or develop a system of reporting treatment effectiveness as outcome measures that could be used by program planners, patients, third party payers and professional associations for potential benchmarking. The Speech-Language Pathology Department at Beaumont, began to develop their own computer based entry and analysis system known as the Beaumont Outcome Software System© (BOSS) [8]. The BOSS developed a series of seven point subjective and objective scales (i.e., 60 scales for adults and children) used to record severity before and after treatment as judged by clinicians. (Appendix II) The intent was to report treatment effectiveness or clinical progress from the time of admission (initial evaluation) to the discharge from treatment. A very friendly computer form of fifteen patient features was developed to enter into the software database. A more sophisticated software (BOSS©, Fred Weiner, PhD) program was developed to analyze the interactive effects of the patient features (i.e., Admission Score & Date, Discharge Score & Date, Age, Gender, Communication Diagnosis, Clinician, Length of Stay, Number of Clinical

Procedures, Charges). [8] A software program was developed for retail distribution and an interface program was developed to allow clinicians to directly enter their BOSS scores on the hospital medical records system. The BOSS was used in our department for eleven years (1995 through 2006) and collected in excess of 20,000 adult and childhood patient outcomes. Our Beaumont Health System has since grown into a 1738 bed multiple medical center organization with a Speech-Language Pathology Department that has over 70 speech-language pathologists providing 60,000 clinical procedures annually. Here is what we discovered.

GRAND AVERAGE OF CLINICAL OUTCOMES (1995-2006) AT SEVEN SITES

Table 1 summarizes the BOSS© outcomes from 1995 through 2006. The Beaumont Speech-Language Pathology Department clinical staff (45 clinicians at the time) reported on 20,000 patients discharged from treatment at seven different clinical sites (i.e., (1) Outpatient Voice and Stuttering Clinics, (2) Center for Children's Speech-Language Disorders, (3) Outpatient Adult Center /Royal Oak, MI, (4) Outpatient Adult Center/Troy. Mi, (5) Inpatient Rehabilitation Unit/ Royal Oak, MI (6) Dysphagia Program /Royal Oak, MI, and (7) Dysphagia Program/ Troy, Mi). Table 1, illustrates the number (N) of patients treated at each site, the average treatment progress achieved on a 7 point scale at each site, the length of stay in days, the number of procedures (evaluation and treatments) and the average discharge status all on a 7 point scale. Clearly there are variations in these outcomes that reflect the severity and nature of communication disorders. Our Dysphagia Programs average only 7-9 days of treatment with 4-5 treatment sessions and achieve a respectable 5.1 on a scale of 7 ("7" describes a normal swallowing performance). Whereas our Center for Children's Speech-Language Disorders reveals a discharge status of 4.6 with an average of 62 treatment procedures over a period of one year (385 days). The outpatient Voice and Stuttering Clinics average the most progress on a seven point scale (5.7) in 57 days with an average of 3 treatment sessions. The Voice and Stuttering Clinics can be described as clinically efficient, that is greater GAIN for the least COST (i.e., Length of Stay and Number of Treatments). Different communication diagnoses not only require different treatment strategies, involve different length of stay but they also produce different clinical outcomes.

It is valuable to compare our inpatient rehabilitation program (Inpt.Rehab/RO) with our outpatient rehabilitation program, treating similar patients with medical diagnoses of Closed Head Injury, Stroke and other Neuropathologies (i.e., Parkinson Disease, Multiple Sclerosis).

The inpatients were treated over a 17 day period and received 18 treatment sessions. They made some progress (1.0 level of movement on a seven point scale) and finished the treatment program at 5.0 (a good discharge scale value).

Compare that to our outpatient adult rehabilitation program where we treated for an average of 68 days (two months) and with 23 treatment sessions and they were discharged at a slightly higher progress level at 5.4 . An outpatient program begins treating patients later after their disease onset and those patients can be seen more often with appropriate reimbursement coverage. These patients are shown to make more progress in a longer

treatment program. Reaching a level of 5 on the progress scale is what we consider a “functional performance level”. Seven would be normal communication skills.

Table 1. Beaumont Outcome Software System © 1995-2006, N: 20,066

Clinic Site	N	Treatment Progress	Length of Stay (days)	Number of Treatments	Discharge Status
Voice & Stu. Clinics	1803	3	57	4.5	5.7
Children’s Center	4343	2.4	385	62	4.6
Outpatient Adults/RO	1212	1.2	68.8	23	5.4
Outpatient Adults/Troy	1533	1	59	16	5.3
Inpatient Rehab/RO	1639	1	17	18	5
Dysphagia Program/RO	4197	3.3	9.9	5.1	5.1
Dysphagia Program/Troy	5339	.62	7.1	4.1	5.1
Grand Mean Values		1.7	86.2	19	5.1
Total Patients	20,066				

Clinical Outcomes (mean values) at Seven Clinical Sites Page 4.

Comparing the two Dysphagia treatment programs in Table 1 it can be noticed that both programs were able to achieve a 5.1 discharge level, which is good functional performance. However the RO Dysphagia program had a longer length of stay (9.9) and greater treatment progress (3.3) with 5.1 procedures. They saw their patients early in the onset of their disability. The TROY program saw them later post-onset and made less progress in fewer days and fewer treatments but still achieved the same Discharge level. The programs were not different in their treatment effect but the patients were seen at different times post-onset.

These grand average clinical outcomes in Table 1 illustrate how different our clinical program strategies need to be to accomplish a good clinical outcome. Some of our programs are considerably more expensive (length of stay or number of procedures) like our Children’s Center of Speech –Language Disorders, when compared to our outpatient Voice and Stuttering Clinics or our Dysphagia programs. Nonetheless, all these services are demanded by our medical community, and we usually succeed at getting all our patients to a Discharge level of 5, which is considered a good “functional level of performance”.

AVERAGE OUTCOMES OF THREE OUTPATIENT CLINICS IN 2000

Table 2 illustrates all the outcomes collected at three very different outpatient sites in 2000.

Table 2. Beaumont Outcome Software System© 2000, Three Sites

Outcome Parameter	Voice & Stuttering	Children's Center	Outpatient Adults
Admission Score	2.74	2.50	4.23
Discharge Score	5.65	4.80	5.28
Clinical Progress	2.9	2.3	1.04
Number of Treatments	4.43	66.6	20.7
Length of Stay	54.1	348.1	64.3
Est.Charges	\$515	\$4482	\$3564
Pt. Satisfaction (7 pt. scale)	6.3	6.7	6.8
N (Completed Treatment)	111 (52%)	185 (36%)	81 (83%)
N (Evaluated Only)	214	516	97

Voice & Stuttering Clinics, Children's Center and Outpatient Adult Program Page 5.

The Voice and Stuttering Clinics were at the medical office building (MOB) and you can see that 111 patients of the 214 that were evaluated, completed treatment. That is a 52% of treatment completion rate. Only the patients who completed treatment were used to score outcomes. These patients were initially, moderately severe in their communication disorder outcome rating (admission score 2.7) and were discharged at a 5.6 level which reflects good clinical progress of 2.9 levels . On average they remained in treatment for 54 days and received 4 treatment sessions. This is an extremely efficient (minimal time and good gain) clinical outcome. The shorter the length of stay and the fewer procedures the less the cost to the patient/payor. We estimated on average in circa 2000 year dollars, a total charge of approximately \$515.00 for this service. If we compare these outcomes to our Children's Center (BMC) we note comparable admission severity (2.5) with good but less discharge outcome at 4.8 and a very long period of treatment (348 days) with 66 procedures and an estimated 2000 year dollar value of \$4482. While we achieve good clinical outcomes with these children it is much costlier to provide these services and achieve the desire outcome. Finally, examining our outpatient adult outcomes (BRHC) we can see that our admission severity level is much less than our Children's Center or our Voice & Stuttering Clinic. These patients have already received inpatient rehabilitation and have made some clinical progress. Their admission severity is 4.2 and they are discharged at a very good 5.3. They required an average of 64 days of treatment and 20 treatment sessions, very likely limited by their insurance caps. The charges in 2000 year dollars was estimated at \$3564.00. Different clinical outcome measures (length of stay, number of treatments, and possible reimbursement) can be used to describe different clinical programs.

CHILDREN'S BOSS© OUTCOMES 2000-2006 BY COMMUNICATION DIAGNOSIS

Chart #1, illustrates the different number of treatment procedures required to obtain a good "functional clinical outcome" (5.0 or better) for a particular diagnosis.

4 Diagnoses by Number of Treatments and Discharge Scores at the Center for Childhood Speech-Language Disorders, Page 6.

Chart 1. Beaumont Outcome Software System © 2000 to 2006, N: 581.

Apraxia of speech in children is a very challenging disorder and in our experience required on average 89 treatment sessions to achieve an outcome of 5.0. Whereas articulation disorders in children required only 38 treatment sessions to obtain a discharge outcome of 5.8, language disorders required more treatment sessions (78) to obtain a discharge score of 4.5. All four childhood communication disorders did well in treatment but each one required a different number of sessions to achieve that outcome. These are important features to discuss with parents when they need to anticipate their costs in keeping their child in a treatment program that is going to have a good outcome.

ADULT BOSS© OUTCOMES IN 2003 BY COMMUNICATION DIAGNOSIS

Table#3, illustrates how different adult communication disorders can exhibit different discharge status outcomes and can require different numbers of treatment sessions and length of stay.

Table 3. Beaumont Outcome Software System© 2003, Adult Outpatients

Communication Diagnosis	Discharge Score	Treatments	Length of Stay	Patient Satisfaction
Aphasia	5.5	19	60	6.4
Apraxia	4.5	15	42	6.2
Dysarthria	5.7	9	29	6.5

3 Adult Communication Diagnoses by Discharge Status, Number of Treatments Length of Stay and Patient Satisfaction. Page 6.

The length of stay (days in treatment) and the number of procedures or treatment sessions can be considered a short hand for the cost to the patient or payor for services. Ideally we want to achieve a positive clinical outcome and leave the patient with a good satisfaction. In Table #3, you can see how treating Aphasia is more time consuming and costlier to the payor/patient than the other diagnoses but we can achieve a very good discharge outcome at 5.5. Apraxia of speech probably had the least effective outcome at 4.5 with 42 treatment sessions. Dysarthria is the least expensive (29 days of treatment) and 9 sessions with an excellent discharge outcome of 5.7. In all three diagnoses, regardless of length of stay or outcome, the patients provided a high satisfaction score (6.4, 6.2 and 6.5).

CLINICAL OUTCOMES IN FIVE COMMUNICATION DIAGNOSES IN THREE DIFFERENT YEARS

Sometimes our success with patients can vary year to year. In Chart #2, we illustrate how treating the same communication diagnosis in three different years (2000, 2003, 2005) can vary. If we examine Vocal Cord Paralysis patients we notice how the clinical outcome (i.e., amount of progress on a seven point scale) only varied from 3.9 in 2005 to 4.2 in 2003, but in the case of Stuttering the clinical progress varied from 1.0 in 2005 to 3.2 in 2000. The Aphasia group, on the other hand varied very little from .9 to 1.3 to .99 in 2000, 2003 and 2005.

These variances in GAIN or clinical outcome progress can be attributed to the admission severity level, comorbidities, discontinuance of treatment or motivational issues on the part of these patients. It is interesting to examine the chart and notice how the Aphasia group tends to maintain a lower stereotypic gain in each of the three years sampled compared to the Stuttering group. These differences may be directly related to the complexity of the communication disorder to be treated.

Variations in Discharge Status by Year and Communication Disorder Page 7.

Chart 2. Beaumont Outcome Software System© Variations in Discharge Status.

WHAT WE LEARNED FROM THE BEAUMONT OUTCOME SOFTWARE SYSTEM

1. Common discharge GOAL of “5” emerges across all diagnoses by clinicians.
2. Length of stay was predictable and was stereotypic of diagnosis, severity, & complexity.
3. Cost was related to LOS.
4. Referral patterns and comorbidity affected outcomes. Early referrals better, late and re-admits worse. Less comorbidity resulted in better outcomes and shorter LOS.
5. Clinician’s experience impacted outcomes. More experienced-- more efficient.
6. Outcomes do not predict Quality of Life or communication competence but they do predict patient satisfaction.
7. BOSS Outcomes could not be compared (benchmarked) to region or nation.
8. Advancing computer technology made data entry, integrated analyses, and large database possible but expensive. The lack of benchmarking without recurring investment and CMS recognition of ASHA NOMS dictated the transition to NOMS.

9. BOSS© outcomes were used: (a) to persuade payors to consider payments for Voice rehabilitation. (b) to demonstrate that clinical progress with Aphasic patients could not be accomplished without a minimal length of stay and treatment sessions. (c) to explain to the hospital administration the variance in clinical outcomes. (d) to demonstrate effectiveness of treatment options for Autism and Down's when costs and length of stay were difficult to manage. (e) to expand staff when clinical value (cost divided by GAIN) was good (f) to meet JCAHO, CMS & BCBS standards of outcome reporting. (g) to argue the need to remove the CMS CAP on post-stroke rehabilitation. (h) to consider Cost-Effectiveness formulas for SLP treatment programs. (i) to facilitate an easy transition to ASHA NOM System

NATIONAL OUTCOME MEASUREMENT SYSTEM© 1997

In 1993 the American Speech-Language Hearing Association began a profession wide examination of treatment effectiveness in all healthcare environs.[9,10] This was undertaken in response to its professional members, third party payors and their patients requests to have a broad based report card of the effectiveness and efficiency of our clinical services. In 1997 after several investigations and the efforts of a national task-force to establish a national data, the National Outcomes Measurement System (NOMS) of the American Speech-Language Hearing Association was developed. [6] The objective of the NOMS database was to demonstrate the “ value of speech-language pathology services ... provided to children and adults with communication and swallowing disorders” . [10]

The NOMS is based on a series of twenty one Functional Communication Measures that are organized as seven-point-equal-appearing interval clinical subjective scales. The seven point scales were standardized and developed with professional clinicians to clearly express the level of functional communication independence. Six of the communication performance scales are designed for childhood communication disorders and fifteen were developed for adults. Each scale delineates a communication function (i.e., articulation, comprehension, voice, pragmatics etc.) critical to identifying the severity of the disorders of communication. Level 1 on the functional communication scale (FCM) is the worst possible performance and level 7 is a normal functional level of communication performance. Each scale was carefully defined and revised to express the optimal agreement amongst professional clinicians as to the level of performance. (Appendix II)

Healthcare organizations with speech-language pathology service programs must register and train each of their clinicians to be certified to use the NOMS data collection system. The NOMS was designed to compare the clinical outcomes for a number of different communication disorders with a variety of demographic features (age, gender, medical disorder, length of stay, reimbursement, number of treatment, service delivery type etc.) . It is also designed to benchmark or compare treatment effectiveness or “value” of services provided between different facilities both regional and throughout the United States.

How are ASHA-NOMS© (est.1997) Different from the BOSS © Outcomes (est.1995)

- a. NOMS measures the per cent of patients that make progress on the 7 point Functional Outcome Scales chosen for communication diagnosis.
- b. BOSS measured the amount of progress that patients made on a 7 point outcome scales chosen for that specific communication diagnosis.
- c. NOMS measures the percent of patients that did not make any progress.
- d. BOSS measured the number of outliers (patients) who scored well below average at a particular clinical site and for a specific the communication diagnosis.
- e. NOMS benchmarks a facility's outcomes to the regional or national outcomes.
- f. BOSS did not benchmark their outcomes.
- g. NOMS uses standardized (21) Functional Communication Measures for all communication diagnoses.
- h. BOSS used sixty seven point scales developed by experienced clinicians specifically related to each communication diagnosis.
- i. NOMS & BOSS both use length of stay, number of treatments, and admission scores to be compared with patient discharge scale scores.

The NOMS values the highly developed Functional Communication Measure as its key to estimating patient progress and clinical effectiveness. It's capacity to benchmark these outcomes to other facilities throughout the nation is unique and clearly advantageous. The NOMS is clearly the most reliable outcome measure and the gold standard in speech-language pathology clinical outcomes.

We learned a great deal from developing and using the BOSS outcome system as it prepared us to immediately adopt the NOMS system as our healthcare outcome system.

WHAT WE ARE LEARNING FROM ASHA- NOMS© AT BEAUMONT

Benchmarking Outcomes

We have been collecting NOMS outcome data for approximately seven years and have become accustomed to examining our outcomes compared to other clinical facilities in the Michigan region and the United States. Although we have only been collecting 3 to 6 year old children's outcomes for the past seven years, we are pleased to see that our clinical services produce as much if not more progress in our patients than the nation. The American Speech-Language Hearing Association, that operates the National Outcomes System (NOMS), provides these comparisons for any period of time that we may choose.

Table 4. NOMS© for Pre-Kindergarten at Beaumont, 2007-2013, N: 382

Pre-K Children 2007-2014	Beaumont	Nation
Articulation/Intelligibility	*86%	76%
Cognitive Orientation	87%	63%
Pragmatics	79%	62%
Spoken Language Comprehension	81%	67%
Spoken Language Production	83%	68%
Grand Average	82%	66%

**Percent of Patients Who Make Progress*

**Bar Graph Illustration of Table 4**

Chart 3. Benchmarked to the Nation N: 6138. Page 11.

In Table 4 we display all of our childhood patient (N:382) outcomes from 2007 through 2013 on four different functional communication measures (i.e., FCM: Articulation/Intelligibility, Cognitive Orientation, Pragmatics, Spoken Language Comprehension and Spoken-Language Production) compared to the national benchmark (N: 6138). In all these FCM's we were able to exceed the average percent of patients making progress compared to the benchmark. We can average all these FCM's and report to our hospital administration that we average 82% for children making progress in our clinical services compared to the nation's 66%. The bar graph below Table 4 easily demonstrates these benchmarked comparisons. While it is comforting to report these clinical outcomes to our hospital and the public, these outcomes can certainly vary by a number of variables including case mix (i.e., different childhood diagnoses) admission severity and time in-treatment (90 days, 6 months or annually). Now that we have collected these large childhood populations rated on the NOMS (i.e., Beaumont N: 382 versus Nation N; 6138, accumulated during a seven year period 2007-2013) we can compare them to six month and twelve month outcomes and begin to consider the possible influences that affect these outcomes.

Table 5 demonstrates the adult outpatient outcomes in this same seven year period for four different Functional Communication Measures (FCM) also benchmarked against the nation, as reported by the American Speech-Language-Hearing Association. We exceed the percent of patients making progress in all four FCM's compared to the nation, but we are within the 95% confidence interval in Motor Speech, suggesting that our 76% and the nation's 73% are comparable or not significantly different. The nation's NOMS scores represent 23,437 patients across all the national facilities using NOMS and our patient population for this interval (2007-2013) is 517. These large differences can create percent progress variations. The ASHA NOMS provides patient demographics and case mix characteristics for the period samples requested. It is important to note that in these two populations, Beaumont's number of cerebrovascular disease patients were 46.6% of our caseload and only 17% of the nation's caseload. Further, our head injury population represented 26.1% of our caseload and only 3.7% of the nation's. Consequently 71% of our patients exhibited Aphasia and 16% presented with Dysarthria, compared to the nation's 11.4% of Aphasia diagnoses and 8.6% of Dysarthria diagnoses. The nation, during this period of time (2007-2013) reported that 59.9% of their adult caseload were treated for Dysphagia and only 9.8% of our patients were treated for Dysphagia. These variations in patient population mix will influence the overall Functional Communication Measures of patient progress.

Table 5. NOMS© for Adult Outpatients at Beaumont, 2007-2013, N: 517

Outpatient Adult 2007-2014	Beaumont	Nation
Spoken Language Comprehension	*82%	66%
Spoken Language Expression	82%	67%
Motor Speech	76%	73%
Memory	83%	65%
Grand Average	82%	69%

**Percent of Patients Who Make Progress*

Bar Graph Illustration of Table 5

Chart 4. Benchmarked to the Nation N: 23,437. Page 11.

LEVELS OF PROGRESS ON THE NOMS©

Another way of possibly examining a facility's clinical effectiveness is to look at the number of patients who are not making any progress. In Chart #3 we illustrate our children's progress over this 2007-2013 period of time on one FCM (articulation/ intelligibility) . Compared to the nation, Beaumont demonstrated a smaller percent of patients making no progress, 13.9% than the nation

24.1%. Further we had a smaller percent of children making one level of progress (28.9%) compared to the nation (38.5%), however we made up for this reduction by demonstrating a larger percent of patients making multiple levels of progress (57.3%) compared to the nation at 37.4%. Our overall percent of children making progress for this FCM was 86.1% compared to the nation's 75.9%. These differences can usually be accounted for by differences in communication disorder diagnosis. Autism Spectrum Disorders and Down syndrome patients will make progress but are unlikely to make multiple levels of progress compared to Articulation and Language disorders.

Per Cent of Children Making Progress Benchmarked to the Nation Page 12.

Chart 5. NOMS© Pre-Kindergarten at Beaumont, 2007-2013. Functional Communication Measure- Articulation/Intelligibility.

POPULATION DEMOGRAPHICS THAT CAUSE VARIATIONS IN NOMS© OUTCOMES

In Table 6 we can clearly see how patient demographic characteristics can alter the potential NOMS score of "Per Cent of Patients that Make Progress". Here we compare a large patient population in our Adult Outpatient Clinics from 2007-2013 (N: 517) to the nation's

patient population (N: 23,537). It is very clear that we see a different case-mix of adults who we treat compared to the nation. While our patient's average age range (60-69) is grossly comparable to the nation (i.e., 21% Beaumont and 16% Nation), our medical diagnoses and communication diagnoses are not similar (i.e., Beaumont at 46.5% CVA and 71% Aphasia, compared to 17.3% CVA and 11.4% Aphasia for the Nation). Further, a significantly larger number of our patients (97.3%) are treated in a 46-90 minute treatment session compared to the Nation (19.6%). We might also have made greater progress with our patients because we treated them on average for a 57 day length of stay and the nation shows only 31 days of treatment. Finally, a large percentage of our patients are discharged directly to home (91.2%) compared to the nation at 38.4%, indicating that our patients did not have to return to the hospital, convalescent facility or skilled nursing facility. Our patients likely had fewer comorbidities and less severe disease and consequently less impairment or disability.

Table 6. NOMS© Demographic Characteristics of Adult Outpatients, 2007-2013 N: 517

Demographic Characteristic	Beaumont Health System	Nation
Age 60-69	21.2%	16.2%
Medical Diagnosis: Cerebrovascular Accident	46.5%	17.3%
Speech-Language Pathology Diagnosis: Aphasia	71%	11.4%
Per Cent of Patients Treatment Goals Met	61.5%	50.6%
Average Number of SLP Treatment Sessions	19.4	13.2
Length of SLP Treatment Session: 46-90 minutes	97.3%	19.6%
Average Length of Stay	53.7	31.3
Discharge Disposition: Home	91.2%	38.4%

Benchmarked to the Nation, N: 23,537 Page 12.

BENCHMARKING BY REGION AND NATION

Another positive feature of the ASHA-NOMS is its capacity to compare our facility outcomes with the local region as well as the nation. These are very helpful comparisons for hospital administrators who are conscious of competition, and our third party payors who may be interested in relative clinical effectiveness and value. Table 7 briefly demonstrates our

per cent of progress outcomes when compared to our Beaumont region (i.e., Michigan, Ohio, Illinois, Indiana and Pennsylvania). The Table demonstrates our Pre-Kindergarten population for the year 2010 on three FCM's (i.e., Articulation/intelligibility. Speech-Language Production, Speech-Language Comprehension). The numbers of patients in each FCM is relatively low as we discharged fewer children in this time period (2010) than usual. It is important to realize that some children are scored on one FCM or multiple FCM's depending on possible comorbidities or their specific communication disorder and the resulting treatment strategy.

The table demonstrates that we have greater numbers of children making progress compared to the Region and the Nation. For the Articulation/Intelligibility FCM we reported 83% of our children making progress and the Region and Nation tied at 75%. For the Speech-Language Production FCM Beaumont exhibited 92% of our children demonstrating progress with 83% for our Region and considerably less for the Nation at 70%. Again, these variations can be accounted for by patient population differences. One of the problems with using FCM's as the main feature of comparison in clinical treatment progress is that it covers a large potential variation in communication diagnoses.

Table 7. NOMS© Reporting Beaumont Outcomes for Pre-Kindergarten 2010

Functional Communication Measure	N	Beaumont % Patients/Progress	Region* % Patients/Progress	Nation % Patients/Progress
Articulation/Intelligibility	54	83 %	75%	75%
Speech-Lang/Production	50	92%	83%	70%
Speech-Lang/Comprehension	35	91%	84%	69%

3 Functional Communication Measures Benchmarked to Region and Nation Page 13.

IMPACT OF THE NUMBER OF TREATMENT SESSIONS ON NOMS© OUTCOMES

There is little disagreement among most clinicians that the more treatment sessions provided and/or allowed for by third party payors will affect the clinical outcomes. Chart 6 examines this premise in our Beaumont Pre-Kindergarten population (N: 382) compared to the Nation (N: 6138). The Chart illustrates that per cent of progress made by Beaumont and the Nation (Green and Red bars) increases with the greater number of treatment sessions provided.

Treatment Sessions by Levels of Progress in Pre-K Children			
	No-Progress	1-L	Mul-L
WBH-Artic./Intell.	12	22	43
WBH-Sp/Lang. Prod.	11	21	36
WBH-Sp/Lang. Compr.	11	20	35
Nation/Artic/Intell.	18	27	38
Nation/Sp/Lang.Prod.	14	21	28
Nation/Sp/Lang.Compr.	12	18	25

Table figures for Chart # 4

Comparing Progress by the Number of Treatment Sessions Beaumont, N:382.
Benchmarked to the Nation N: 6138 Page 13.

Chart 6. NOMS© Pre-Kindergarten 4 Functional Communication Measures, 2007-2013.

The “no –progress” (blue bar) for all FCM’s at Beaumont and the Nation also demonstrates that fewer treatment sessions were provided. The green bars or the multiple levels of progress designation clearly is correlated to the greater number of treatment sessions reported. These types of reports are extremely important in demonstrating to physicians, administrators, payors and politicians that cutting back the number of treatment sessions by staff reductions, failure to approve continuing treatment or reimbursement clearly reduces the demonstrated potential outcome gain.

COMMON CLINICAL ISSUES DEFENDED BY OUTCOMES

I. Dysphagia Outcomes Differ at Two Different Clinical Settings

We discovered several years ago that our swallowing rehabilitation programs at our main hospital (1070 beds) and our satellite hospital (418 beds) had noticeably different clinical

outcomes. Analysis of our collected outcome data allowed us to observe that our larger, Level One Trauma hospital saw their swallowing patients within 8-10 hours of referral and began treatment immediately to prevent aspiration and to establish safe swallowing protocols. They also continued swallowing treatment after transfer to the acute inpatient rehabilitation unit.

The smaller community hospital clinicians saw their dysphagia patients 1-2 days after referral with less measured severity, in some cases, due to apparent spontaneous improvement. The staff was able to provide safe swallowing and diet recommendations and were able to discharge them without as much intervention. The outcomes revealed that patients seen earlier after referral were given more treatment due to a more severe admission level. These outcome findings suggest that each clinical environment has its own special patient care protocols depending on specific patient needs.

II. Therapy CAPS for Aphasic Patients

As has been stated earlier in this chapter, our outcome data, as well as a number of studies demonstrates that fewer treatment sessions with patients experiencing aphasia, produces lower discharge outcomes.[4,5] Our outcome data suggests that a treatment program with 25-30 treatment sessions for speech and language pathology produces important gains in functional communication ability. Certainly, after 30 treatment sessions the outcome gain slows but is functionally significant. Recently, Medicare caps, limitations on treatment, for aphasic patients have been implemented nationwide. It is our opinion that, NOMS clinical outcome data, when used to analyze improvement for this and other populations of neurologically impaired patients, clearly demonstrates that these caps significantly diminish the potential for recovery or critical functional speech and language skills. It should be noted that CMS recognizes NOMS as an approved outcome measurement system. [7].

III. Third Party Voice Treatment Guidelines

Payors have asked us if we could demonstrate, with our population of voice-impaired patients, the optimal number of treatment sessions to produce maximum gain or benefit to the patient. Apparently there were providers who seemed to bill for an unusually high number of treatment sessions for certain diagnoses. We were able to submit NOMS and BOSS outcome data that included mean length of stay and mean number of treatments, for a number of different vocal pathology diagnoses for a number of outpatient adults. This data has been very helpful in obtaining treatment pre-authorization for patients in need of vocal rehabilitation.

IV. Employer Monitoring of Quality Measures in Health Care

All hospital settings monitor quality of care. Our facility has asked all the clinical service departments to present evidence of clinical quality metrics and we have used our clinical outcomes in this regard for the past twenty years. For some departments this has meant costly acquisition of outcome measurement systems. We developed the BOSS© system in 1995 and then transitioned to the ASHA NOMS© in 2006 at virtually no cost to our department. Our

hospital administration has readily accepted our NOMS outcome system and we often use these data to make the case for expanded resources. Our hospital system has asked us to simplify our outcomes reporting system and with the NOMS we can produce “grand average” dashboards or report cards that easily give us the ability to demonstrate and explain variations.

V. Answers Patient Questions on Clinical Prognosis

What clinician can say that they have never been asked the following questions by a patient:

How long will this treatment program take?
How many visits will be needed?
How much will this cost me or my payor?
Can I recover my normal functional voice, speech or language?
What increases my likelihood of a good clinical result?

Since we have used the BOSS© (1995) and the NOMS© (2006) we have been able, in certain clinical environments, to turn to our computers in the clinic and answer these questions. For example, we can tell a patient: from our outcome analyses in the past five years, that a person with vocal cord nodules has, on average, received 5-6 individual treatment sessions over a period 90 days and obtained a specific clinical improvement level. That usually means on a scale of 7 being normal, the patient is likely to achieve a 5, or better in this time frame. We can also tell them that sometimes age, medical comorbidities and initial severity may influence this outcome. This has been a valuable clinical feature that can foster confidence and motivation in our patients.

CONCLUSION

Life is like riding a bicycle.
To keep your balance you must keep moving.
Albert Einstein, in a letter to his son Eduard, February 5, 1930 [11]

Clinical outcomes can be extremely important to clinical programs when building the case for measuring the value of speech and language rehabilitation [4, 5, 6,2]. Outcome data collection can be used to demonstrate the critical benefits of our services to physicians, third party payors, administrators, government health care planners and our patients. [12] We can use outcome data to analyze and justify clinical programs by comparing effectiveness, efficiency and overall value. This information will be important as speech and language pathology is integrated into both national health planning initiatives and local accountable care organizations.

Clinical outcomes are not interpreted on “face value”. They must be reported carefully with appropriate benchmarking and in sufficient numbers (reliability and correlation power)

to be persuasive. They will be more effective when reported overtime, not in “brief periods” with no comparisons.

Clinical outcomes are powerful tools if carefully used. [4, 5, 9] They can be misinterpreted and rejected if not carefully presently and justified. The Beaumont Outcome Software System© (1995) was an early computer software program which attempted to account for treatment effectiveness over a ten year period of time in a large hospital based program. We learned some important lessons using the BOSS© and honed our skills at collecting and interpreting clinical outcomes. However, we were unable to benchmark our outcomes with local, regional or national programs. Further, we could not maintain the large and growing database in our hospital medical records system. The American Speech-Language Hearing Association’s development and maintenance of their National Outcome Measurement System was an excellent service to the profession. Reporting clinical outcomes does not replace our extensive and growing professional armamentarium of standardized tests and assessments for a large variety of communicative diagnoses. [1, 2] In the future, the inevitable expansion of software and computer technology will allow us to develop even more analyses of patient performance, demographics and progress. Our profession must remain aware of these developments and make every attempt to harness these opportunities for the long-term benefits of our patients [2, 10].

Chapter 29

**VELOPHARYNGEAL FUNCTION AND SPEECH:
ANALYSIS OF SURGICAL OUTCOME
IN YOUNG ADULTS WITH REPAIRED CLEFT PALATE
AND RESIDUAL VELOPHARYNGEAL INSUFFICIENCY**

***Mirta Palomares*, Drina Alvarez, Carlos Giugliano
and Carolina Villena***

Fundacion Dr. Alfredo Gantz, Santiago, Chile

ABSTRACT

The protocol for the evaluation and treatment of young adults with cleft palate at a Cleft Palate Center in Santiago, Chile is described. All the patients studied with this protocol were young adults present with residual velopharyngeal insufficiency (VPI) after palatal repair. All patients underwent a complete speech evaluation. Surgery for correcting VPI was planned individually in each case according to findings of videonasopharyngoscopy (VNP). All cases were operated on with a superiorly based pharyngeal flap. The surgical procedures were performed by the same surgeon in all cases.

Surgical outcomes of velopharyngeal function (VPF) were analyzed with postoperative VNP and a speech evaluation.

Patients with normal articulation before surgery showed adequate VPF one month after the pharyngeal flap was performed. None of these cases required Speech & Language Pathology (SLP) treatment.

None of the patients with compensatory articulation disorder (CAD) preoperatively showed adequate VPF one month after the pharyngeal flap operation. All these cases required SLP treatment including biofeedback with VNP. After a six-month period of SLP treatment and biofeedback, sixty – three percent of these patients achieved similar results as the group of patients with normal articulation before surgery. After a follow-up

* Corresponding Author Email: mpaloma4@hotmail.com.

period of 6 months, a total of 79% of the cases showed satisfactory results of VPF during speech. Most patients showed good compliance and motivation for treatment.

Keywords: Cleft palate; Speech; Surgery

INTRODUCTION

Velopharyngeal Insufficiency (VPI) refers to any structural alteration of the soft palate and the pharyngeal walls where there is not enough tissue for a complete closure of the velopharyngeal sphincter (VPS) during the production of oral phonemes [1]. The percentage of patients with residual VPI following cleft palate (CP) repair varies from center to center, but in general it is estimated that 10 - 20% of patients with cleft palate will present with VPI post palatal repair. [2-4]

The presence of residual VPI affects various parameters of speech and voice resonance. The characteristic symptomatology is the presence of obligatory errors including: hypernasality, nasal emission, weak oral consonants and compensatory articulation disorder (CAD). [5]

Several surgical techniques for correcting VPI have been described. The selection of a specific technique for each patient depends on closure pattern as observed by videonasopharyngoscopy (VNP) and videofluoroscopy (VF). The most commonly used surgical techniques for correcting VPI include: Modified Orticochea's pharyngoplasty or lateral flaps operation; surgical increase of the posterior pharyngeal wall; superiorly based pharyngeal flap; and secondary surgical repair of velar muscles. [6]

It has been reported that surgery for correcting VPI yields better outcomes when it is performed at an early age, ideally before entering the preschool system, when communication demands increase. At this stage, around 4 years of age, children have usually acquired a greater number of phonemes and show better compliance for performing procedures which allow a full assessment of VPF including an instrumental evaluation of the VPS through VNP and VF. It has been reported that when VPI is corrected early, there is an improvement in over 90% of the cases. [7]

CAD refers to speech errors derived from unconscious patient attempts to produce a phoneme, usually a high intraoral pressure consonant sound. In these cases, articulation placement is displaced closer to the sound source, usually to the pharynx or the glottis. The most common compensatory errors are: the glottal stop and the pharyngeal fricative. [1] CAD is present more frequently in patients with severe VPI [8]. CAD significantly affects intelligibility.

In cases of CAD, prognosis is less favorable since speech sound errors are incorporated into Linguistic rules. Thus, it becomes much more difficult to change brain motor engrams, affecting surgical outcome and extending the total time of Speech & Language Pathology (SLP) intervention [1]. It has been described that articulatory placement and manner are more malleable at earlier ages. Therefore, even in cases of CAD, surgical correction of VPI can decrease total time of SLP treatment. Also, correcting hypernasality can provide more confidence for developing speech skills and abilities. [9, 10]

Currently, there are health programs and international organizations that promote and support early and timely care of patients with cleft palate (CP). Centers with more experience and better results usually perform the primary surgeries of lip and palate before one year of age. Early repair of the palate is recommended in order to minimize speech disorders. [11] Unfortunately there are patients that for various reasons do not have access to multidisciplinary treatment, thus hampering rehabilitation and integration into society.

Young adults with CP usually have an increased frequency of social, occupational and emotional limitations. [12] These limitations negatively affect the rehabilitation process. In these cases, CAD, VPI, palatal fistulae, abnormal dental occlusion and septal deviation are common findings. All these factors significantly affect quality of life [13, 14].

Some reports studying adult patients describe that there are no significant changes in the speech intelligibility following VPI surgery. This finding seems to be related with the articulatory errors that directly affect VPS motion during speech. Even with an appropriately planned surgical treatment, hypernasality is corrected in only 75% of the cases. [8]

Hamlen (1970) pointed out that poor surgical result in adults can be associated with greater difficulty for acquiring and using new speech abilities, as well as lack of family support. [15]

Several strategies can be used for the management of CAD including: Phonological approach; auditory biofeedback; and biofeedback with VNP. Traditionally it has been described that most patients with CAD respond positively to conventional speech intervention. Witzel et al, (1989) demonstrated that patients with velopharyngeal dysfunction associated with CAD undergoing pharyngeal flap, achieved a consistent closure of the VPS in connected speech after biofeedback therapy using VNP. [16]

Endoscopic feedback would be indicated for patients who do not respond to conventional intervention or those who are progressing too slowly. Fast and consistent positive results have been reported in patients with CAD who have undergone endoscopic biofeedback. With the use of this technique, CAD can be corrected in a few sessions. It has been reported that endoscopic biofeedback therapy seems to be superior to conventional intervention for treating velopharyngeal dysfunction associated with CAD. [17]

Direct visualization of the VPS supports articulation therapy creating a greater impact on the patient, improving learning and reducing total time of therapy. [16,18]

Young adults with residual VPI require an interdisciplinary management which basically considers the same procedures for evaluation and treatment as used in children, but with some modifications in its application, considering anatomical and emotional differences, as well as self - motivation.

The purpose of this chapter is to describe a protocol for treating VPI in young adults, considering individualized surgical planning and SLP intervention.

MATERIALS AND METHODS

Patients

Patients were recruited at the Fundacion Dr. Alfredo Gantz in Santiago, Chile, from 2005 to 2013. All cases who met the following inclusion criteria were included in the study group:

patients with cleft lip and CP or isolated CP; older than 17 years; without associated syndromes; with normal hearing; present with residual VPI after initial palatal repair; without fistulae; without further surgical procedures for correcting VPI other than the initial palatal repair.

All cases were assessed by the cleft palate team. They were guided by personal motivation and they committed themselves to undergo all necessary evaluations and interventions.

Speech Assessment

Each patient was evaluated before and after the surgery by the same Speech & Language Pathologist at the Fundación Gantz. The professional conducting the evaluations had more than 10 years of clinical experience in the evaluation and treatment of patients with craniofacial anomalies.

Severity of the VPI, presence of CAD and size of the gap as observed by VNP before the surgical procedure were assessed.

It should be pointed out that before performing the VNP, all patients should be able to produce at least 2 high oral pressure consonant phonemes with adequate placement during the repetition of syllables and isolated words. Therefore, SLP treatment was provided before the procedure whenever it was considered necessary to do so.

The VPI was classified according to the severity of the hypernasality and nasal emissions (Table1).

Table 1. Classification of VPI according to severity

VPI Severity	VPI Symptomatology
Without VPI	Normal Velopharyngeal Function; absence of hypernasality *; No nasal emission.
Mild VPI	Mild hypernasality - nasal turbulence.
Moderate VPI	Moderate Hypernasality – as perceived during the production of vowel sounds. Audible nasal emissions during production of most of the high pressure consonant phonemes.
Severe VPI	Severe hypernasality during the production of vowel sounds and oral consonant phonemes. Nasal emission in all high pressure consonant phonemes. Low pressure in oral consonant phonemes. Facial grimaces or movements associated with nasal emission.

* Severity of hypernasality was classified according to a previously reported 4-point scale [18].

Speech was classified according to the presence or absence of CAD. No CAD was considered as the condition in which the patient had normal articulation placement in all speech contexts, despite the presence of hypernasality; CAD was considered when articulation placement was abnormal in different contexts such as repetition of syllables, words, sentences and automatic or spontaneous speech.

Instrumental Evaluation of VPI

Pre and post-operative evaluation of the VPI was performed by VNP. A flexible scope with a diameter of 3.5mm at the tip was used. This procedure was carried out by the same Otolaryngologist and SLP in all cases. A standardized speech sample was used including isolated phonemes, connected speech, automatic speech and sustained fricative phoneme sounds [19]. All procedures were recorded for a thorough further analysis. Size and shape of the gap and velopharyngeal closure pattern during speech were assessed. Ten-percent gaps or bubbling without a discernable gap were considered as small gaps. Gaps larger than 10% but less than 40% were considered as medium size gaps. Gaps larger than 40% were considered as large gaps.

Surgical Procedure

Each surgical procedure for correcting VPI was planned individually according to findings of VNP. In order to prevent postoperative airway obstruction, other factors were also considered for designing the surgical plan, including adenoid and/or tonsil hypertrophy, and nasal septum deviation.

A superiorly base pharyngeal flap would be indicated in cases present with circular or sagittal patterns. The width of the flap was designed to match the maximum displacement of the lateral pharyngeal walls during the production of the speech sample.

A lateral flaps pharyngoplasty would be indicated in cases with a predominantly coronal shape of the gap. Posterior Pharyngeal wall increase using cartilage or fat was used in cases with coronal or circular gaps not greater than 10%.

Post-surgical complications were assessed in all cases.

Speech Therapy Post-Surgery

Postoperative SLP treatment was implemented according with the SLP evaluation which was routinely performed one month after surgery in all cases. Patients with satisfactory outcome of speech and VPF did not receive further treatment. However, they were followed up monthly for a period of 6 months. Patients with postoperative unsatisfactory outcomes as determined by presence of CAD and/or present with incomplete velopharyngeal closure during speech received SLP treatment including 2 modalities: Articulation placement

intervention provided in a 45-minutes session once-per-week and a separate biofeedback 30-minutes session also once-per-week.

The intervention addressing articulation placement and manner was aimed to correct abnormal articulation patterns and carry over adequate articulation into connected speech. Initially, imitations and repetitions strategies were used. Further on, generalization strategies were used in order to enhance carrying over into connected speech. These strategies included reading aloud, singing, conversational speech, and role – play. [16]

Biofeedback therapy included recognition and identification of velopharyngeal structures on the VNP image; analysis of VPS motion during swallowing, blowing and speech; and finally, analysis of VPS motion during the production of oral consonant phonemes with best and worst velopharyngeal closure. Also, during the biofeedback sessions, some of the strategies used during the articulation intervention were also incorporated as velopharyngeal motion was being observed on the screen.

Discharge

The criteria for definite discharge were: normal articulation placement and manner during conversational speech and normal VPF in different speech contexts.

Ethical Aspects

This study was approved by the Ethics Committee of Fundación Gantz. All patients were recruited in this Center. The study was conducted in accordance with the ethical standards of the 1964 Helsinki Declaration. Each patient was carefully briefed about the diagnostic procedures, the surgical procedure that would be performed and the eventual subsequent SLP treatment that would be provided. All patients signed an informed consent before being accepted as participants.

RESULTS

Fourteen surgical procedures were performed. All patients were older than 17 years of age. Seven patients were males and 7 patients were females. Age range was 17 – 35 years of age. Mean age was 24 years of age. No intraoperative or immediate postoperative complications were detected.

All cases studied for this protocol presented with a circular pattern. Thus, all cases were operated on with a superiorly based pharyngeal flap. No other surgical procedure was performed in this series. Three patients were operated on with a narrow flap; six patients were operated on with a medium flap; and 5 patients required a wide flap. The width of the flap was designed to match maximum lateral pharyngeal wall displacement during speech as observed by VNP. (See Table 2).

Table 2. Patient's characteristics and results of the pre and postoperative evaluations

Patients	Age (years)	Cleft Type	Presence of CAD	Preoperative VPI Severity	Preoperative size of the gap (%)	Selected flap width	Postoperative VPI (1 months)	VPI severity after SLP treatment (6 months)	Discharged
1	22	UCLP	Yes	Moderate	20	Medium	Moderate	Without VPI	Yes
2	20	CCP	No	Mild	10	Narrow	Without VPI	-	Yes
3	17	ICP	Yes	Severe	50	Width	Moderate	Without VPI	Yes
4	17	ICP	No	Moderate	30	Medium	Without VPI	-	Yes
5	34	BCLP	Yes	Severe	80	Width	Severe	Mild	No
6	18	UCLP	Yes	Severe	70	Width	Severe	Mild to moderate	No
7	24	BCLP	No	Mild	10	Narrow	Without VPI	-	Yes
8	35	UCLP	Yes	Moderate	40	Medium	Severe	Mild	No
9	23	UCLP	No	Mild	10	Narrow	Without VPI	-	Yes
10	20	CCP	No	Moderate	30	Medium	Without VPI	-	Yes
11	32	CCP	Yes	Moderate	40	Medium	Mild	Without VPI	Yes
12	20	BCLP	No	Moderate	20	Medium	Without VPI	-	Yes
13	26	BCLP	Yes	Severe	80	Width	Severe	Without VPI	Yes
14	23	UCLP	Yes	Severe	80	Width	Severe	Without VPI	Yes

Key: UCLP = unilateral cleft lip and palate, BCLP = bilateral cleft lip and palate, ICP = incomplete cleft palate, CCP = complete cleft palate.

Forty-three percent of the patients studied for this protocol did not show CAD preoperatively. All these cases demonstrated adequate VPF as determined by the SLP assessment one month postoperatively. All these cases did not require any further treatment and were discharged.

The remaining 57% of the cases demonstrated CAD preoperatively. None of these cases were able to achieve adequate VPF one month postoperatively (See Table 2). All these patients underwent further postoperative SLP treatment and biofeedback with VNP. Five out of these 8 cases achieved adequate articulation and VPF after an intervention period of 6 months. Finally, the remaining 3 cases which persisted with inadequate VPF and/or abnormal articulation placement showed mild or moderate hypernasality during spontaneous – connected speech. One of these cases demonstrated a flap with scar tissue which decreased the width of the flap. In this case, by using “forced” articulation placement during the production of isolated words, both ports of the flap looked practically occluded as observed by VNP. However, during spontaneous – connected speech, both lateral pharyngeal walls failed to make tight contact with the lateral – free borders of the flap causing hypernasality and inconsistent nasal emission. Another patient presented with a very narrow flap which could not achieve complete closure not even during the production of isolated words. This case required a new surgical procedure.

Finally, the third patient presented with a flap with an apparent adequate width, good lateral walls motion but it was not possible to achieve a complete seal during connected speech after 6 months of SLP intervention and biofeedback sessions. This patient did not return for a follow up visit in which further surgical treatment would have been discussed. It should be emphasized that these 3 cases with postoperative residual hypernasality and nasal emission demonstrated CAD and a severe VPI preoperatively.

In the overall analysis of the group of patients studied for this chapter, seventy-nine-percent (11 of 14) of the cases achieved a satisfactory outcome following the pharyngeal flap operation and a period not longer than 6 months of postoperative SLP treatment including biofeedback sessions with VNP.

CONCLUSION

The purpose of this chapter was to assess speech and VPF outcome in young adults undergoing surgery aimed to correct VPI.

Poor results have been reported in adult patients who undergo pharyngeal flap surgery [11], hence leading some cleft palate teams to question the implementation of surgery for correcting VPI in this age group. However, a higher success rate (80 - 90%) was reported [20] when general population including children and adults were studied. Another report [8], describes that in young adults, an adequate surgical planning before performing a pharyngeal flap can increase the success rate up to 75%.

The results of this chapter show that 43% of young adults showed improvement of speech and VPF one month following pharyngeal flap surgery. All of these cases were from the Group of patients without CAD. This percentage rose to 79% after SLP intervention aimed to correct CAD including VNP biofeedback.

A relationship between CAD and lateral pharyngeal wall motion has been reported in several papers. [13-14, 16] This could explain why SLP treatment and endoscopic biofeedback increase velopharyngeal closure after a tailor made pharyngeal flap. Moreover, an aberrant lateral walls movements with outward displacement during the production of some fricative phonemes has been reported in cases of CAD [21]. Endoscopic biofeedback seems a safe a reliable tool for correcting this abnormal velopharyngeal motion during speech. In the group of patients studied for this chapter, patients without CAD demonstrated mild VPI with sizes of the gap equal or below 30%. (See Table 2).

It has been reported that endoscopic biofeedback can increase lateral walls motion [22]. Thus, the closure pattern can be modified from a circular pattern into a more sagittal pattern. In the patients studied for this chapter, 5 cases managed to successfully mobilize the lateral pharyngeal walls during speech, resulting in a significant improvement in their speech and VPF. As described by Witzel et al. (1989) [16] some patients have the potential to increase movement of the lateral pharyngeal walls with adequate training. However, it should be pointed out that some of our patients failed to achieve adequate lateral pharyngeal walls motion despite the use of endoscopic biofeedback. Moreover, some of our patients were able to increase motion during the production of isolated words but they were not able to consistently carry over this improvement into conversational speech.

Correction of CAD should consider the use of effective strategies of SLP intervention. In adult patients, the use of biofeedback therapy with VNP seems a valuable tool which can provide a direct visualization of the VPS during speech. Patients undergoing this procedure usually increase awareness of VPS motion which facilitates carrying over the improvement into conversational speech. Also, the integration of auditory and visual inputs effectively decreases total time of the SLP intervention. [23]. Nonetheless, it should be considered that endoscopic biofeedback is an additional tool which should be used as a complement to conventional strategies aimed to correct articulation placement.

When articulation strategies including endoscopic biofeedback are used for 6 months following pharyngeal flap surgery, patients with CAD can achieve similar final outcomes as those of patients who did not present CAD preoperatively.

Adult patients often present with various physical and/or functional alterations in addition to preferences and motivations that are usually related with social aspects and job issues. [12-14] Some patients prefer an intervention for improving communication skills, whereas others are more motivated to improve aesthetic appearance, and dental occlusion. It is important for the cleft palate team to consider the individual needs and points of view of each patient. In the group of patients studied for this chapter, all patients sought treatment by personal motivation and the most common goal was to improve communication.

From the results described in this chapter, it is evident that VPI in young adults should be addressed with a specifically designed treatment plan. Anatomy of the palate, degree of VPI, presence of CAD, size of the defect, and patient motivation should be carefully assessed in each case.

The implementation of the Protocol described herein can provide a better guide for diagnosis and treatment. Thus, an appropriate surgical and SLP intervention plan can be designed, improving final outcome.

From the analysis of the group of young adults studied for this chapter, it seems that those patients present with VPI and CAD who do not show an appropriate motivation for

following the long term management program, cannot be considered good candidates for surgery.

Although the results described for the group of young adults analyzed for this chapter are promising, it will be necessary to study larger groups of patients with different characteristics in order to support the conclusions of this study. It should be emphasized that young adults with appropriate personal motivation for improvement have an acceptable chance for a favorable outcome. However, as mentioned herein, the best results seem to be associated with absence of CAD preoperatively, as well as the presence of small and medium sizes of gap at the VPS during speech.

Chapter 30

STRATEGIES FOR TREATING PHONOLOGIC DISORDER IN CHILDREN WITH CLEFT PALATE

Maria C. Pamplona¹ and Santiago Morales²

¹Hospital Gea González, Tlalpan, Mexico City, Mexico

²The Penn State University, University Park, PA, US

ABSTRACT

Children with cleft palate (CCP) may be at risk for articulation disorders. These articulation patterns are known as compensatory articulation disorder (CAD) and are generally regarded as compensatory behaviors secondary to velopharyngeal insufficiency (VPI).

Some authors consider these behaviors as a phonologic disorder.

Whole language principles consider that there is an interaction between the phonological rules and other language rule systems. An articulation problem is far more complex in nature than a phonetic analysis would suggest, and during intervention, phonologic information should not be separated from the other areas of language, such as pragmatics or syntax. Thus, within the same activity, several pieces of information about all areas of language, including phonologic information are provided.

Scaffolding strategies can be useful for correcting placement and manner of articulation. Sometimes, it is difficult to know which strategy would be best option for a specific moment. Few authors have specified the expected time to apply each strategy in order to improve effectiveness. However, when studying the efficacy of these strategies for treating CAD in CCP, some result more adequate depending on the specific stage of speech development or severity of articulation impairment.

In this chapter some scaffolding strategies for phonologic intervention will be described and some ideas for using them in communicative situations in relationship with higher organizational levels of language processing.

Keywords: cleft palate, speech, language, rehabilitation, therapy

INTRODUCTION

Articulation disorders in children may be either phonetic or phonologic in nature. Phonetic disorders are related to inaccurate learning or anatomic, physiologic or/and motor deficits. In contrast, phonologic disorders are considered to be linguistically based and reflect difficulty in the child's organization and representation of the sound system of language. [1 – 3]

Children with cleft palate (CCP) may have an articulation disorder. Certain articulation disorders are generally regarded as compensatory behaviors secondary to velopharyngeal insufficiency (VPI). These errors include dysfunction not only of the velopharyngeal sphincter, but also of the entire vocal tract and higher levels of articulation control in the central nervous system. [4, 5] For example, plosive sounds such as /p/ or /k/ might be attempted by substituting a glottal stop. These abnormal articulation patterns are usually referred as compensatory articulation disorder (CAD). CAD severely affects intelligibility and usually requires a prolonged period of speech therapy. [6, 7]

COMPENSATORY ARTICULATION: PHONETIC OR PHONOLOGIC IN NATURE?

Several authors have described that cleft palate patients are at risk for phonetic based problems due to the structural deviations associated with clefting. [8, 9] However, cleft palate children may be also at risk for phonologic disorders. [10]

A phonetic disorder occurs when the movements of the articulators, such as the lips, tongue, palate, or resonating cavity are altered from a normal or typical production. A compensation such as glottal production or CAD would be considered phonetic, as the child with velopharyngeal insufficiency attempted to produce the sound in an alternative manner to compensate for the inability to establish intraoral air pressure because of the cleft. [10] Because the glottal production reflected an obvious and productive compensation, the problem was viewed as phonetic and articulation became the main topic in intervention. However, only a small or moderate percentage of children with repaired cleft palate exhibit CAD. Most patients, following the repair, produce the more typical pattern and no articulation delays or deviations are seen. [6]

The finding that a small percentage of patients continue to produce CAD despite the early and effective repair of the cleft suggests that some factor other than the inability to establish sufficient intraoral air pressure is contributing to the development and maintenance of this articulatory pattern. Most of the palatal repairs are completed between 12 and 18 months of age, or at the time when first words appear. The appearance of words suggests that by this age children are already establishing a phonological system, or a set of linguistic rules that map the phonetic patterns of speech to the sound and syllable patterns of meaningful language. Thus, what had been a compensatory strategy for approximating sounds heard in the environment during early stages of babbling for some patients becomes incorporated into the phonological rule system before the surgery is completed. Following surgery, when the child is quite capable of producing the plosive sounds or other speech patterns in a more typical manner, the child continues to produce the CAD form because it had become integrated with

the language rules instead of the correct pattern. At this point, what began as a phonetic compensation had become a phonological rule. As a generative and productive rule, the articulatory production would not change until the rule is changed, despite the change in the physical capability to produce the sound correctly.

Evidence for the contention that many of the speech problems of cleft palate children are phonological rather than phonetic can be found in two studies. Chapman in 1993, compared articulation errors produced by children with cleft palate to age-matched and younger groups of typically developing children using a phonological analysis. A phonological analysis examines errors for patterns, such as deleting or modifying sound production patterns according to regularities or "rules." Her findings indicated that children with cleft palate produced the same types of phonological process errors as the younger typically developing children, but they maintained these process errors longer than the age-matched peers. She also found that the children with cleft palate used the phonological process of backing with greater frequency and for more sounds than did the typically developing children. She concluded that these findings suggested that the articulation errors of children with cleft palate were of the same phonological nature as the typically developing children, and that the high occurrence of backing indicated that compensatory gestures had become incorporated into the phonological rules of the subjects. [10]

In the second study, Pamplona et al, in 1999, treated children with CAD following surgery in either a phonetic or a phonological treatment approach. In the phonetic approach children were taught correct production of the error sounds through modeling and reinforcement, using a repetitive drill for a single phoneme until it was mastered. In the phonological condition, multiple errors were targeted simultaneously by focusing on a process, such as producing phonemes in a more frontal position. Thus, three phonemes that had been produced as a glottal stop, such as /k/, /t/, and /p/ were treated simultaneously as sounds requiring more frontal posturing. The phonemes were taught and practiced in a meaningful language context such as storybook reading. Results indicated that while both groups improved their speech, the phonological group achieved normal speech production on average one year sooner than did the phonemic group, which required 2 1/2 years of therapy. Addressing the phonological rules resulted in faster learning of the target productions and more rapid incorporation into the language rules and thus more immediate carryover into conversational speech. [6]

These findings suggest that many of the articulation problems in children with repaired cleft palate currently viewed as phonetic may actually be phonological as early as one year of age. It also implies that during speech assessment and intervention, some additional phonologic analysis and specific strategies should be employed.

Speech intervention in CCP with a phonetic approach considers articulation learning as a specific time of motor learning. Moreover, errors in articulation must be seen as disruptions at some level of the relatively peripheral articulatory processes. Consequently, some therapy procedures are based almost exclusively on the notion that articulation errors are due to faulty control of the articulators. [11, 2] In contrast, in a phonologic approach the children must learn more than just a set of complex articulatory patterns associated with words. They must learn a complete system of phonology. Furthermore, several authors have proposed that some central, cognitive-phonological processing must be included in any description of phonological acquisition. [1, 2]

WHOLE LANGUAGE MODEL. INTEGRATING PHONOLOGY IN A WHOLE

The phonological approach for treating compensatory articulation disorder in cleft palate patients does not necessarily reject well-established principles underlying traditional approaches for articulation disorders. In contrast, articulation must be recognized as a critical aspect of speech sound development under any theory. Consequently, phonological principles should be considered as adding new dimensions and a new perspective to an old problem, not simply as refuting established principles. [2]

Because the phonological system is integrally integrated with the language system, and because faster progress was made when treatment for CAD was more successful when conducted in the meaningful language context of storybook reading, it is also suggested that the language of children with CAD should also be assessed. Hoffman, in 1992, stated that children's speech sound production and perception errors are related not only to phonological knowledge, but also to higher organizational levels of language processing. He also mentions some research findings indicating that children who have difficulty learning phonology also show similar difficulties for learning morphological, syntactic, and semantic regularities of language as well. Hoffman and his colleagues in a series of studies showed that children with phonological disorders made greater progress in both articulation and in language measures such compared to children in treatment approaches that focused on phonological patterns practiced outside of a meaningful language context. [3, 12]

Other researchers have identified language problems in children with cleft palate, including syntax (i.e., grammar), morphology, and vocabulary. [4, 13 – 15]

These findings suggest that many of the language problems actually exhibited by children with CAD may be overlooked when the speech disorder is viewed from a phonetic rather than a phonological perspective. In many cases, there is an interaction between the phonological rules and other language rule systems, so that an articulation problem is really far more complex in nature than a phonetic analysis would suggest.

Pamplona and Ysunza (2000) also found a relationship between CAD and the child's language system, including the ability to use semantic, syntactic, and discourse elements of language rules to express meaning. In this study, they found that children with CAD differ in their overall development of language, and not just speech productions, from children with repaired cleft palates that do not show the CAD speech patterns. These findings suggest that it would be reasonable to provide children with CAD with a more global treatment including linguistic aspects. Treating only the articulation disorders does not seem enough for these patients. It seems more appropriate to consider higher levels of language including abstract thought and reading and writing activities. [16]

For understanding the interaction between CAD and higher levels of language organization we have to consider that children learn language in the context of events such as eating or bathing routines. [12] As they learn the rules, actions and objects are associated with the events, they map words to the visual event. These words would include many levels and descriptions of the ongoing actions and related objects.

Once the words are integrated with the event, they serve to add complexity and abstraction to the internal event structure. Caregivers use language to help the child understand the sequence of the event, as in "we have to wash your hair first. Now let's rinse

the soap out. Then we will get dry". These temporal words have no visual referent. Rather, they are learned by first perceiving a word that has no known meaning to the child. This process of acquiring meaning through context results in the acquisition of abstract language such as interpretations and inferences. [12] It also leads to greater complexity in discourse structures, as the child uses the words to discover temporal and causal links between actions within an event.

In this model, speech productions have an origin independent of the event structure, involving auditory and motor input and output. During infancy, the child's productions increasingly approximate the sounds of the language heard by the child. [18] During this phase, children with cleft palate would use compensatory strategies to best match the output to the input they heard. Children with better-developed event structures would make the transition from prelinguistic sounds productions such as babbling and jargon faster and more efficiently than children with fewer or more impoverished event structures. That is, the event structures have to be present to provide a context for mapping or learning language. These children would map the standard speech produced by others with event. The phonological rule system thus would develop consistent with this adult input. Once children had surgical repair of the palate, their speech productions would change to better match the accurate perceptions and phonological rules.

Children with fewer or more impoverished event structures would continue with prelinguistic sound productions longer. Further, without event structures they would have no context for mapping the speech produced by others with meaning. The compensatory productions would lack a meaningful context for change and therefore would become overlearned motor patterns. As event structures and the concomitant language were acquired, these learned productions would be incorporated into the phonological rule system. That is, the child would continue to match his established speech productions to the adult model. This would result in misperceptions of words and interfere with the processing of higher levels of language, or words learned within the event and linguistic context. CAD should thus contribute to maintaining the language delay. At the same time, the language delay and the incorporations of compensatory productions into the phonological rule system would serve to maintain CAD long after these speech modifications were physiologically necessary.

In fact, the children with CAD frequently demonstrate difficulty with both the event structures and the concomitant language. Many of the children could neither play productively with the toys nor interpret more than the most familiar early events (i.e., bathing) from pictures. Similarly, many times they do not demonstrate elaborated knowledge of events structures in the discourse analysis, marking neither temporal nor causal sequences of actions. Without the development of elaborated and complex event structures, a context for learning the language of interpretations and inferences would not be available. With these principles in mind, some methodologies for language and speech intervention suggest that language and speech should be presented in an integrated manner in order to introduce significant contexts for learning all linguistic elements.

Whole language is a teaching/learning philosophy that recognizes phonetic and phonology as an important component of a whole, assuming that language is indivisible. This teaching philosophy proposes that phonologic information should not be separated from the other areas of language, such as pragmatics or syntax. Thus, within the same activity, all areas of language, including phonology are provided. In this kind of intervention, the production of relevant speech sounds is taught and reinforced within communicative situations. Whole

Language also validates some constructivist principles that guide the evaluation and intervention. [18] These principles suggest that children learn best when:

Language is used to talk about meaningful information and to accomplish purposes that make sense to the child; children are active participants in their own learning, not passive, quite listeners; learning involves repeated opportunities to interact and explore complex information; learning occurs in a context that is sensitive to the needs of individual children and that supports risk taking; language is “whole”; that is, it is presented in a context of meaning and use, not broken up and analyzed in small parts within an artificial setting; children use language to relate to one another and to become socialized as part of culture and community.

Treating only the CAD does not seem enough for these patients. It seems more appropriate to consider higher levels of language including abstract thought and reading and writing activities. In these contexts, phonologic information is integrated with all linguistic areas within communicative purposes and situations. In this order of ideas, the production of speech sounds is not the only goal. The goal is to become effective communicators. In this kind of intervention, the production of relevant speech sounds is taught and reinforced within communicative situations in relationship with higher organizational levels of language processing. [3] The use of abstract and complex levels of language that leads to a coherent and structured discourse can be facilitated in different teaching/learning contexts such as storybook reading. Storybooks are a perfect context for stimulating cognitive and language development in children. [12] Stories have all the elements of the narrative and discourse structure, including the relationships that provide order and structure such as temporality, causality or perspective. Also, they provide stability for seeing those relationships and for working on specific language needs such as articulation patterns of words and/or sounds. Other activities that promote working with speech and language in an integrated way are art, cooking, music or symbolic play.

Pamplona, et al, studied the rehabilitation of children with CAD within naturalistic contexts, following whole language teaching/learning philosophy principles. In this study, it was hypothesized that the most significant change would be concerning the phonologic system. This was not entirely true. Patients from the experimental group, who received therapy according to whole language philosophy, changed dramatically their overall language performance including their phonologic productions. All patients with CAD showed linguistic performance below the expected level according to chronological age. After the intervention period, besides phonologic improvement, children changed dramatically their overall language performance. [19]

STRATEGIES FOR ENHANCING PHONOLOGY

When intervention is based on the phonological principles, some implications for the assessment and management of children with cleft palate may be assumed, including analysis of phonologic processes in addition to phonetic analysis, and the use of facilitation strategies aimed to modify the phonologic system of each child.

The use of strategies seeks to scaffold the child's communicative turns to increase the child's speech and language performance. [3]

These strategies serve to assist the child in formulating messages with greater complexity, specificity of meaning, accuracy, and clarity of expression. Scaffolding strategies consists of various types of prompts, questions, information, restatements, and other procedures that provide support to the child as he/she is actively engaged in the process of communicating a message. [20]

Many phonologists have described specific strategies for facilitating a better way to communicate and/or articulate the sounds of speech. [2, 21] However, few of them have specified the expected time to apply each strategy in order to improve effectiveness. Some of the most common used strategies for are the following: Modeling, [3, 22] Phonemic Cues, [20] Minimal Pairs, [2, 23] Cycles, [21] Imitation and drills, [24] Requests for clarifications, [25] Phonetic changes, [20] and Expansions, [3] among others.

Phonological acquisition is gradual. [21, 26] It is a process. For assessment and intervention, it is important to understand the system of each child, and to recognize in which step of the process is at the moment. A clinical scale of severity of CAD in cleft palate children had been used for this purpose. [27] This scale describes what the child is doing and the difficulty he/she has to manage each specific sound of speech in order to correct placement and manner of articulation. This scale has been useful for understanding the specific moment in the process of each child. It also establishes the degree of severity of CAD in each patient, and facilitates setting intervention goals.

The scale mentioned herein is described as follows:

- *Appropriate articulation.* The patient is able to produce adequate placement and manner of articulation during spontaneous speech, including non-present situations.
- *Inconsistent articulation.* The patient shows compensatory articulation errors inconsistently during spontaneous speech. Intelligibility is not significantly affected
- *Articulation within context.* The patient self-corrects articulation when using speech within a specific context. For example during telling a story from a story book which the patient already knows well. Nonetheless he shows frequent compensatory errors during spontaneous speech.
- *Articulation with strategies.* The patient can correct articulation during isolated words or selected short phrases, only when the clinician uses specific phonologic strategies.
- *Articulation of isolated phonemes.* The patient is able to correct articulation only in isolated phonemes through direct instruction.
- *Constant CAD.* The patient is not able to correct articulation not even in isolated phonemes and despite direct instruction.

Pamplona et al. (2012), studied if some of the strategies commonly used in speech therapy for correcting compensatory articulation errors in children with cleft palate, could be more effective, depending on the degree of severity of CAD. In this study, the following strategies were used during speech therapy sessions: [28]

- A. *Modeling:* Modeling is one of the most reported strategies. The speech pathologist models the speech and/or language behavior that the child is to learn. Some clinicians found that children respond spontaneously if the language behaviors being stressed

are at the child's level. Thus, they model the behavior but do not normally request or formal elicitation. Modeling approaches the normal conditions of language learning more closely than the elicited imitation procedure. [22] Example: Child: “_all he_ (call her)”. Clinician: “Yes, call her”. This strategy has been often described as useful for language development, but it is also proposed as a phonologic strategy. Hoffman states that the models of appropriate articulated words in context are thought to help stimulate appropriate syllabic and phonemic organization. [3] The clinician has the opportunity to model and talk about the phonological structure of words within an overall communicative context. [29]

- B. *Modeling with stress*: With this strategy, the speech pathologist models targeted sounds of speech, but includes a brief pause before the sound and also, a stress on the sounds (phonemes) the clinician wants to model. [28] For example, during a play situation in which a cake is being cut, the child says “_ut the _ae_ (cut the cake); The clinician can respond “yes, (pause)...cut the (pause)...cake. I will (pause)...cut the (pause)...cake and give you a (pause)...piece”.
- C. *Cloze procedure with phonemic cues*: With this strategy, the clinician prompts the child's communicative turn by supplying part of the utterance and letting the child fill the rest. [30] If necessary, the clinician can provide the selected sound of the target word. [20] For example, when reading a storybook, the clinician can say: “Yes, she was hungry, and she found three bowls of sss ____ (soup) on the t t ____ (table)”.
- D. *Phonetic changes*: The speech pathologist indicates that the message would be more easily interpreted with a modification in speech production. [20] For example, when the child says “the _en (the pen)” reading a storybook in which there are different objects, the clinician says: “the pen”. Remember to put your lips together and make an explosion: p p pen”. With this strategy, the information would directly contribute to refining the phonemic distinction being articulated.
- E. *Think aloud in phonemic awareness*: This is a metacognitive strategy where the speech pathologist verbalizes thoughts while reading a selection, thus modeling the process of comprehension. [31] This strategy enables to demonstrate the patient how to select an appropriate articulation process at a specific point in a particular communicative message. The clinician verbalizes specific think-aloud about different levels of Language organization including phonologic information. [28] For example, before reading a storybook, the clinician says: “Let us think which sounds we will be focusing on. We have to consider that some sounds are short and explosive like /k/, /p/, /t/. I will write these letters for reminding us to use them while we refer to the ideas and words of the book. Besides, we have other sounds that are long and continuous: /s/ or /f/. I will write these letters in this other paper. While looking at the storybook, the clinician is focusing on the target sounds and explaining the characteristics of each phoneme and how changing the sound can change the characteristics of the word increasing intelligibility.

For evaluation, all patients were recorded on videotape during speech therapy sessions and the methodology followed is called “narrative-centered themes”. [18] This procedure provides naturally occurring contexts for acquiring world and everyday knowledge. It also serves as a means for addressing children's language and articulation, and allow for an

extended exploration of a general concept. For this purpose, a main topic was chosen, and all activities were structured around this main topic. The goal was to work all linguistic areas in an integrated manner. Thus, articulation goals were always present in an organized whole. Most activities were realized as event representations such as play or storybook reading.

Children were divided in small groups depending on the age, linguistic development, and cognitive level.

All strategies were used within structured activities to provide children with contextually appropriate opportunities to use language and focus on articulation. The speech language pathologist (SLP) could choose either to expand an expression or refine upon an expressed idea by giving specific information, but anyway, SLP made sure that all strategies under study were used with each patient during the sessions.

SLP also used verbal expansions to provide children with information about higher levels of language organization. This type of interaction has been shown to increase the semantic and syntactic complexity of children's utterances, and could have similar effects upon children's phonological productions. [3]

All interactions were video recorded for later transcription and analysis. The examiners quantified the positive changes in articulation elicited by the use of each strategy. Positive changes were considered as the conditions in which the patients were able to approximate or correct appropriate placement or manner of articulation of the phonemes being used. The different strategies were compared in order to determine whether some strategies were more adequate for specific levels of severity of CAD.

Results demonstrated a significant relationship between effectiveness of all strategies and degree of severity of CAD in CCP. All the strategies yielded a significant higher number of positive modifications in articulation in patients classified in the milder levels of the scale, including patients with inconsistent compensatory errors during spontaneous speech and patients who were able to correct articulation within a familiar linguistic context. Moreover, there were a reduced number of positive changes in patients classified in the more severe levels, including patients who were able to correct compensatory errors during the production of words or short sentences, when they were being provided with specific instructions on placement and manner of articulation and patients who were able to correct compensatory errors only during the production of isolated phonemes, through direct instructions.

Hodson, who has largely contributed to the understanding of the phonologic principles in speech assessment and intervention, states that it is important to describe exactly what the child is doing, this allows providing a focus for more efficient remediation procedures. [21] Moreover, in order to achieve an efficient intervention, the SLP has to consider all the communicative emissions of the patient, including subtle changes in his/her speech during the interaction. This will allow the understanding of all linguistic rules interfering with the child's process for correcting articulation.

As a results of the study, strategies that included direct instruction such as phonetic change, cloze procedure with phonemic cues, and/or think aloud in phonemic awareness, appeared to be more effective for promoting positive changes in articulation in patients who were in the higher levels of severity of CAD, such as those who can only articulate correctly isolated phonemes or used them in words or short phrases with the support of the clinician. That is when these strategies were compared with those that do not include direct instruction such as modeling or modeling with stress, a significant difference was observed. However, these two strategies showed similar effectiveness in the lower levels of severity of

articulation. In such levels, children articulate better and are more aware of the use of speech sounds, and show confidence for producing these sounds during a more structured discourse.

It is important to emphasize that modeling is one of the most frequent strategies described. [2, 3, 20] Also, the two strategies that included modeling -modeling and modeling with stress-, were the most common strategies used by the speech pathologists in the study. The results showed that these strategies do not seem to be as effective as the ones that include direct instruction when they are used in children with higher levels of severity of CAD. This finding has important implications for speech intervention. The clinician should consider the characteristics and level of severity of articulation impairment before deciding which strategy should be used.

It should be pointed out, that in the study, for speech intervention, different activities were structured in order to facilitate changes in the phonologic system of each child. Some of them had a structured context such as storybook reading/telling where the text or illustrations provided concrete information with visual cues to refer to. Also, talking about a graphic organizer was considered a structured and present context. In contrast, communicating during symbolic play situations in which the context or situation for playing had to be created with words, or talking about a non-present situation, were considered less structured linguistic context or event, since there were no visual cues supporting communication. In these instances, the individual has to create the whole context through language (decontextualized situation). When the positive changes in articulation elicited by the use of the strategies mentioned above, were compared in more structured and less structured contexts, there seemed to be similar positive changes in both situations. Nonetheless, when the strategies that do not include direct instruction on articulation such as modeling, or modeling with stress were being assessed, there seemed to be a tendency for more positive changes when the strategies were being used in more structured contexts, such as storybook reading / telling. This finding can be explained since these structured situations can provide more contextual or concrete support for communication. This can be especially relevant for the higher levels of severity of CAD, and speech pathologists should consider it for intervention. Moreover, when children with articulation errors are treated, providing visual support is a valuable tool for scaffolding.

In a later study, Pamplona and colleagues studied the efficacy of the strategies for treating CA in CCP. [32] In this occasion they compared two different ways for using scaffolding strategies during intervention in CCP. Both groups received speech therapy aimed to correct compensatory articulation according to the principles of the Whole Language Model where storybook readings were the main context for intervention. Intervention was aimed to reinforce correct speech sounds while enhancing cognitive linguistic organization.

Within these main principles of intervention, in the first group (control group), the SLP used the strategies described before for phonologic intervention. The SLP was instructed that all strategies should be attempted in each case. In contrast, in the second group (experimental group) the SLP used the same phonologic strategies, but they were selected according with the level of severity of CAD as assessed by the scale described herein. [28] (See table 1). When comparing the levels of advance in both groups, a Mann Whitney test showed a significant difference that indicates a greater advance in the experimental group. In conclusion, considering the characteristics of the phonologic system of each child can be useful for facilitating the selection of some strategies, which may be more effective than others in any particular case. Moreover, the dynamics involved in each strategy were

analyzed. Some strategies appeared to be more appropriate for different stages in the natural process of correcting a compensatory articulatory pattern in CCP.

Table 1. Use of strategies according to the level of severity of CAD

Level of articulation	Characteristics of the level The patient:	Strategies
Constant CA	Is not able to correct articulation not even in isolated phonemes and despite direct instruction.	Phonetic changes, Think aloud in PA.
Articulation in isolated phonemes	Is able to correct articulation only in isolated phonemes through direct instruction.	Phonetic changes, Cloze proc with PC, Think aloud in PA
Articulation with strategies	Can correct articulation during isolated words or selected short phrases, only with support of the clinician.	Phonetic changes, Cloze proc with PC, Think aloud in PA, Modeling with stress.
Articulation within context	Self-corrects articulation within a specific context. Shows frequent CA errors during spontaneous speech.	Modeling with stress, Modeling.
Inconsistent articulation	Shows CA errors inconsistently during spontaneous speech.	Modeling with stress, Modeling.
Appropriate articulation	Is able to produce adequate placement and manner of articulation during spontaneous speech.	

The results of these two studies suggest that when speech strategies are used according to the severity of the compensatory articulatory pattern (which is classified depending on the frequency of its appearance during speech and the response to correction prompts), it seems easier for the child to follow the speech pathologist lead in order to correct the pattern.

Patients who are able to produce a correct articulatory pattern only on isolated phonemes or short words, with consistent prompting are more likely to show an effective response to direct instruction on placement and manner of articulation. A possible explanation is that these patients show a limited level of phonologic awareness. In contrast, strategies, which use modeling and modeling with stress seem to be effective in patients with lower degrees of severity of CAD. These patients appear to be more aware of the characteristics of the speech sounds.

It can be concluded that selecting the speech pathology treatment strategies for each case, according with its specific characteristics, including the severity of the articulation disorder, as assessed by its use in conversational speech and the response to prompting, can become a valuable procedure for improving outcome during speech intervention.

INTERVENTION

Considering that language is indivisible, and that learning occurs from whole to part to whole, intervention should treat all areas of language within meaningful contexts according to the child's level of development. These contexts are based in more / less familiar events and allow focusing on the target sounds and language structure or organization.

The intention is to create a natural environment for language learning. The activities have to be carefully designed to be consistent with whole language principles of learning where language is an integral part of every activity. The lessons are organized to help children make sense of complex information while they acquire and use language. This allows CCP to focus on speech and language learning while they do interesting and fun activities.

One strategy is to expose children to a wide variety of books some which include a repeatable and predictable text, others that have great and explicit drawings, and finally, others which challenge listening and critical thinking abilities because of their more complex and abstract story and/or content. It is described that storybooks are great for stimulating cognitive and language development in children. [18] Storybooks have all the elements of the narrative and discourse structure, including the relationships that provide order and structure such as temporality, causality or perspective. Also, the information in the illustrations and the language used in context provide stability for seeing those relationships and for working on specific language needs such as articulation patterns of words and/or sounds. For children with CAD, having both, visual and phonologic information in a simultaneous way can enhance better results. [28]

Other activities that promote working with speech and language are art, play, cooking, and music.

STORYBOOK READING

Strategies

In order to choose the right storybook each child has to be carefully evaluated to get to know his/her linguistic level and phonologic preferences. Knowing the system of each child allows the SLP to interact in an adequate level according to his/her developmental characteristics.

During storybook reading the different aspects of language that required special attention in CCP must be addressed. At the beginning, the story and the illustrations give context for constructing meaning by talking about the actions, characters or sequence of the story. Repeated readings or redundant ideas are useful for understanding and organizing the information as it become familiar. These familiar contexts will facilitate focusing in articulation in a meaningful way while acquiring complex and structured language. In other words, the story is the whole that will allow working with patterns or specific sounds, and then these specific parts will be integrated again in the whole. By modifying the child's internalized rules governing production, the child's speech changes to match this revised category. Because the phonological rule is integrated with other aspects of language, occurrence of correct sounds in spontaneous production is more rapid. [20] The sound does not first have to be learned as a motor production and then generalized to language and spontaneous speech. All areas of language work together as a complex system moving into integration.

Different strategies must be used during storybook reading. These strategies can be used before, during and after reading in order to provide tools for constructing meaning and focusing in specific parts such as the sounds of speech.

Before reading, activating prior knowledge or predicting about the story can help to focus on meaning and start constructing the topic. Also, talking about the target sounds is useful for developing awareness and get ready for articulating during the task.

During the storybook reading two major goals are to be established. First, pay attention to the structure and content of the story for enhancing linguistic organization, and second, to practice and work with the target sounds in articulation. For linguistic organization helping the children to follow the story and make connections, predictions, interpretations or inferences in order to help them see the relationships and conclusions. For articulation, using strategies like the mentioned before or focusing on the target sounds by analyzing words or patterns could help the child to match events with words and sounds for improving articulation and developing phonemic awareness. This would facilitate generalization into connected speech. Finally, after the storybook reading, many activities for responding to the story can be developed such as: use/make graphic organizers for analyzing the narrative structure of the story (beginning, problem, end); analyzing a character or the setting; analyzing feelings, solutions; making art or representing the story or parts of the story. This will allow focusing on articulation as the topic becomes familiar by reading, analyzing and talking about it. During the whole reading, emphasizing the target sounds would allow to hear those sounds in a context of use and develop awareness about their contribution for creating meaning.

Many authors who follow phonologic principles recommend a set of strategies aimed to facilitate changes in phonologic processes. Some of these strategies are based on phonologic development in infants and toddlers. Some of these strategies are to be used during intervention for enhancing stimulation in CCP and CAD. Hodson, in 1991 stated that children with highly unintelligible speech can discriminate others productions, but seem to discount their own auditory feedback signals, even when hearing is judged to be within normal limits. The author suggests providing auditory stimulation during speech therapy sessions for enhancing the development of this ability. [21] This auditory stimulation can be provided if the sounds are stressed and identified during the storybook reading. The purpose is to help the child to rely on auditory feedback and metalinguistic knowledge while following the structure and information of the story and illustrations. In this process, self-monitoring skills are enhanced.

Ingram, studied phonologic development. He described that children learn best the sounds that are necessary to their language, and these sounds are the ones that appears frequently. [26] Modifying linguistic context in order to make the target sounds appear frequently can help children to focus on those sounds and practice articulation while following the plot or event.

CONCLUSION

In conclusion, working articulation within a linguistic whole may be a perfect context for intervention with CCP. Naturalistic contexts such as play or story telling allow for event structures and related language to be examined for semantic context, discourse organization and situational representation while focusing on the sounds of speech.

In these situations, selecting the speech pathology treatment strategies for each case, according with its specific characteristics, including the severity of the articulation disorder, as assessed by its use in conversational speech and the response to prompting, can become a valuable procedure for improving outcome during the speech intervention.

Chapter 31

PHONETIC AND PHONOLOGICAL DIFFICULTIES ASSOCIATED WITH EXPRESSIVE LANGUAGE IMPAIRMENT IN YOUNG CHILDREN: A REVIEW OF THE LITERATURE

Dilara Deniz Can¹, PhD and Eileen Brudish², MA, CCC/SLP

¹University of Washington, Seattle, WA, US

²Calvert County Public Schools, Prince Frederick, MD, US

ABSTRACT

Specific Language Impairment (SLI) occurs in 6.3% of children, twice as much in males than females (Pinborough-Zimmerman et al., 2007). The typical range of prevalence of SLI during the preschool/early school years is between 2% and 8% with an overall median prevalence of 5.95% (National Institute on Deafness and Other Communication Disorders, NIDCD, 2010). SLI involves delays or deficits in expressive or receptive language development, or both (Mursepp, Aibast, Gapeyeva, & Paasuke, 2014). In the case of the expressive language impairment (ELI), children's language is characterized by small vocabularies; short, incomplete sentences; and confusing or disorganized conversations (Mursepp et al., 2014). ELI may involve difficulties with the form of language (phonology, morphology, syntax), the content of language (semantics), and/or the function of language in communication (pragmatics) (American Speech-Language-Hearing Association, ASHA, 1993).

Deficits in phonology may include difficulties with early speech sound production, and/or weak phonological awareness skills (i.e., rhyming, sound isolation, segmentation, and blending), resulting in struggles with reading and writing (ASHA, 2015). Deficits in morphology and syntax may include late use of word combinations, shorter utterances in words with errors often occurring on verbs (especially verb endings, auxiliary verbs, and past tense marking of regular and irregular forms), function words, pronouns, plurals, and later-developing prefixes/suffixes with difficulties in reading and understanding the meaning of words (ASHA, 2015). Impairments in semantics may include poor vocabulary use; word-finding difficulties; using synonyms/antonyms, multiple-meaning words, and figurative language (e.g., idioms, metaphors, proverbs, humor, poetic language); poor organization of narratives and expository discourse that impacts ability to

convey intended meaning (ASHA, 2015). Difficulties in pragmatics may include difficulty expressing ideas, feelings, and personal experiences or difficulty initiating/sustaining conversations (ASHA, 2015).

The purpose of this chapter is to review the most relevant research published that informs the definition, identification, and treatment of expressive language impairment (ELI) in children ages 3 to 10 years, with a focus on phonetic and phonological interventions. Early identification and treatment of ELI is crucial for several reasons. First, the Common Core State Standards Initiative (2015) emphasizes the importance of oral language and learning to read and write. Grade-specific morphological awareness standards begin to appear as early as 1st grade, specifically in the areas of Language Knowledge, Vocabulary, and Reading Phonics/Word Recognition (Smith Gabig & Zaretsky, 2013). Second, adequate phoneme awareness appears critical to speech production and early reading success for children with speech impairment (Macrae & Tyler, 2014; Nathan, Stackhouse, Goulondris, & Snowling, 2004; Rvachew, Nowak, & Cloutier, G., 2004).

Targeted areas of intervention for expressive language deficits (ages 3 to 10) include but are not limited to phonological interventions such as increasing consonant repertoire, decreasing the use of phonological processes (e.g., final consonant deletion, fronting), and enhancing phonological awareness skills (e.g., rhyming, blending, segmenting, and elision) (ASHA, 2015). Timely implementation of such interventions, wherever the existing language skills may be on the expressive communication continuum, will benefit children's short-term as well as long-term language, literacy, and social-emotional skills (Greenwood et al., 2013; Hawa & Spanoudis, 2014; Poll & Miller, 2013; O'Hare, 2013).

1. INTRODUCTION

1.1. Specific Language Impairment with a Focus on Expressive Language Deficits: Definition and Prevalence

Expressive language deficits in children can lead to multiple diagnoses, since the terminology in the field that relates to language disorders is mixed. Similar symptoms that characterize significant delays in expressive language abilities can either be classified under a type of Specific Language Impairment (SLI) (Tomblin et al., 1997), or, they can be presented as evidence that an individual is affected by a "language disorder" (American Psychiatric Association, Diagnostic and Statistical Manual of Mental Disorders, DSM-V, 2013). Specific language impairment (SLI) is a form of developmental language impairment in which children demonstrate age inappropriate difficulties with the acquisition of language (Tomblin et al., 1997). SLI involves delays or deficits in multiple language domains (i.e., expressive language, receptive language, or both), in the absence of observed mental retardation, nonverbal cognitive deficits, neurological and sensorimotor deficits, hearing loss, and environmental deprivation (Muursepp et al., 2014; Leonard, 1998). Schwartz (2009) defined SLI as an impairment of language comprehension, language production, or both, in the absence of hearing impairment, general developmental delay, neurological impairment, or autism spectrum disorder. Children with SLI may have deficits in different language skills (e.g., phonology, morphology, syntax, semantics, and pragmatics) (Tomblin et al., 1997; Schwartz, 2009). Many children with SLI demonstrate deficits in vocabulary development,

such as late talking, having a smaller and less varied vocabulary size, and word finding and learning problems, in general (Leonard & Deevy, 2004). Vocabulary development deficits (i.e., lexical acquisition deficits) are strongly associated with oral and written language development and thus, particularly devastating for young children's social communication skills (Catts, Fey, Tomblin, & Zhang, 2002; NICHD Early Child Care Research Network, 2005). The first purpose of this chapter is to define expressive language impairment, and review the most relevant research evidence that informs the identification and treatment of expressive language deficits in young children (ages 3 to 10). The second purpose of this chapter is to review the role of phonetics and phonology and related aspects (e.g., vocabulary, morphology, syntax) in expressive language deficits in children, and implications of the intervention research for clinical and educational practice (e.g., speech/language therapy, curriculum development, teacher training, etc.).

Impairment and disorder are terms that are used interchangeably in the literature (Greenwood et al., 2013; NIDCD, 2015). Language disorder, in general, is defined as a communication disorder characterized by persistent difficulties in the acquisition and use of language across modalities (APA, DSM-V, 2013; ASHA, 1993 & 2015). According to DSM-V (i.e., Language Disorder, diagnostic criteria, 315.39, F80.9), language disorder is associated with reduced vocabulary, word knowledge as well as word use; limited sentence structure due to grammatical and morphological deficits; and impairments in discourse such as the ability to use vocabulary and connect sentences to have a conversation, or to explain/describe a topic or series of events. According to the guidelines provided by ASHA (1993, 2015), a language disorder is impaired comprehension and/or use of spoken, written, and/or other symbol systems. The disorder may involve deficits with the form of language (phonology, morphology, syntax), content of language (semantics), and the function of language in communication (pragmatics). Language disorders usually affect vocabulary and grammar, which then limit the capacity for discourse (APA, DSM-V, 2013). Expressive ability, specifically, refers to the production of vocal, gestural, or verbal signals (APA, DSM-V, 2013).

While no clear statistics are available, to our knowledge, regarding the prevalence of expressive language impairment in young children, most statistics are provided on the prevalence of communication disorders or specific language impairment in general (O'Hare, 2013; Pinborough-Zimmerman et al., 2007; Tomblin et al., 1997). O'Hare (2013) reports that communication disorders of preschool children affect 5-8% of those aged between 2 and 4.5 years. The findings of Pinborough-Zimmerman et al. (2007) within a very large sample, approximately thirty thousand children, showed that communication disorders occurred in 6.3% of 8-year-old children. Tomblin et al. (1997) reported that SLI impacts approximately 7% of monolingual 5-to-6-year-old children. Other statistics within younger children show that approximately 15% of children at age 2 present slow onset and progression of expressive language (Desmarais, Sylvestre, Meyer, Bairati, & Rouleau, 2008; Horwitz et al., 2003; Hawa & Spanoudis, 2014). In 18- to 23-month-old toddlers, the percentage of late talkers is estimated to be around 13.5% whereas in 30-36 month-old toddlers the rate rises to 17.5% (Horwitz et al., 2003).

1.2. The Correlates of Expressive Language Impairment and Rationale for Their Study in Relation to Other Language Domains

Language impairments in children may co-occur with other communication disorders (Macrae & Tyler, 2014). For example, children with language impairments may have a co-occurring speech sound disorder (SSD), which is the most common communication disorder type on pediatric speech-language pathologists' caseload (Broomfield & Dodd, 2004; Tyler, Lewis, Haskill, & Tolbert, 2003). Statistics show that 50%-75% of preschool children with speech sound disorders and approximately 14% of 6-year old children with speech sound disorders have a co-occurring language impairment (Shriberg & Kwiatkowski, 1994; Shriberg, Tomblin, & McSweeney, 1999). In comparison with children with SSD alone, children with co-occurring SSD and language impairments have been shown to exhibit poorer auditory discrimination (Nathan, et al., 2004), phonological awareness (Nathan et al., 2004), phonological memory (Lewis et al., 2011; Sices, Taylor, Freebairn, Hansen, & Lewis, 2007), vocabulary (Lewis et al., 2011), narrative abilities (Wellman et al., 2011), and less developed reading, spelling and written language skills (Nathan et al., 2004; Macrae & Tyler, 2014).

Children with co-occurring SSD and language impairments may be diagnosed with a more severe SSD than children with SSD only (Sices et al., 2007). These children may also show differences in the error patterns they use (Macrae & Tyler, 2014). Errors patterns, also referred to as *phonological processes*, were described in theory of natural phonology as reflecting "mental substitutions which systematically but subconsciously adapt phonological intentions to phonetic capacities" (Donegan & Stampe, 1979, p.126; Macrae & Tyler, 2014). According to Stampe (1969), infants' first words likely reflect the full range of these phonetic restrictions on speech output. As children are exposed more and more to the adult forms, they gradually suppress these patterns so that their word productions match the adult form. Children who fail to suppress the error patterns may be diagnosed with SSD.

Two types of speech error patterns that reflect distinct underlying deficits in children with SSD are *atypical error patterns* (i.e., simplifications that are not used by children with typical phonological development) and *omission error patterns* (i.e., omission of a syllable or phoneme; weak syllable deletion, final consonant deletion, cluster reduction). Atypical error patterns reflect poor phonological processing skills and weak underlying phonological representations (Leitao, Hogben, & Fletcher, 1997; Preston & Edwards, 2010). Phonological processing includes specific operations such as encoding, storage, retrieval, production, and explicit awareness of speech sounds (Leitao et al., 1997). Omission error patterns may reflect an underlying cognitive-linguistic processing deficit in children with SSD (Shriberg et al., 2005). The argument is that frequent use of omission patterns is consistent with a genetically transmitted cognitive-linguistic processing deficit, while substitutions and distortions indicate at least partial underlying knowledge of the target phoneme, and phoneme deletions may indicate lack of phonological representation of the targets (i.e., to be able to appropriately encode, store, and retrieve them) (Shriberg et al., 2005). In a study by Macrae and Tyler (2014), within a sample of young children ages 3 to 5 years, children with co-occurring SSD and language impairments showed different types of speech error patterns than children with SSD only. More frequent use of omission error patterns and less frequent use of distortion error patterns were observed within children with co-occurring SSD and language impairments. This finding supported Shriberg et al. (2005) conclusions that frequent omission

pattern use may be associated with a more compromised linguistic system characterized by absent phonological representations for target sounds.

In sum, the speech of children with co-occurring SSD and language impairments may be characterized by several error patterns, including omission, distortion, typical and atypical error patterns (Macrae & Tyler, 2014). Frequent use of atypical patterns is associated with poor phonological awareness skills, and poor reading and spelling skills, and therefore has been linked to a phonological processing deficit (Macrae & Tyler, 2014). Omission patterns, on the other hand, are assumed to reflect absent phonological representations for target sounds and perhaps a more global cognitive-linguistic processing deficit in contrast to atypical patterns (Macrae & Tyler, 2014).

While language impairment may co-occur with speech sound disorders (Broomfield & Dodd, 2004), several studies have shown that SLI is linked to slow processing speed (Leonard, 1998; Chen & Liu, 2014), and abnormalities in the brain structures involved in procedural memory, such as Broca's area, the basal ganglia, the supplementary motor area (SMA), and the cerebellum (Gauger, Lombardino, & Leonard, 1997; Tallal, Jernigan, & Trauner, 1994; Ullman, 2004; Vargha-Khadem et al., 1998). Given the comorbidity of expressive language impairment with other communication disorders and the link between SLI and structural abnormalities in the brain (Marini, Tavano & Fabbro, 2008), it becomes even more crucial to study aspects of language impairment, theories that explain the potential causes of SLI, and interventions developed to treat the symptoms.

There are two major traditional theories of SLI that demand attention (Evans, 2001). Competence-based theories of SLI are based on the assumption that language impairments seen in children with SLI are the result of incomplete knowledge, missing rules, principles, or incomplete linguistic constraints (Gopnik, 1990; Gopnik & Crago, 1991; Rice & Wexler, 1995). Performance-based accounts of SLI, in contrast, are based on the assumption that the language impairments in children with SLI are secondary to nonlinguistic processing impairments (Evans, 2001). Several processing-based accounts of SLI, for example, assume that "general processing capacity limitations" can account for the greater weaknesses in grammatical morphology seen in children with SLI (e.g., Bishop, 1997; Leonard, 1998).

In addition to "general processing deficit" accounts of SLI, other processing-based accounts of SLI assume a deficit in a "specific processing mechanism" that secondarily affects the language system more broadly. For example, Gathercole and Baddeley (1990) have argued that a deficit in the child's ability to store phonological information in working memory is responsible for the lexical deficits seen in children with SLI. Alternatively, Tallal et al. (1996) argue that SLI is not due to deficits in phonological memory, but, due to deficits in temporal processing. They argue that an inability to process rapidly changing aspects of the acoustic signal results in the language problems exhibited in children with SLI (Tallal et al., 1996).

In the early 2000s, an alternative view of SLI proposed that the contributions of both the child and the environment create a multi-dimensional system of interacting components (Evans, 2001). From this alternative perspective, the distinction between competence and performance disappears, and an emergent account of SLI predicts that changes in extrinsic contextual demands will result in changes of the language behaviors that children exhibit (Evans, 2001). According to this dynamic view, under certain circumstances, the child's language behavior will be stable and predictable, and under other conditions, it will be highly

variable, such that moment-to-moment variability will be displayed based on changes in external contextual demands (Evans, 2001).

Given the comorbidity of SLI with other language disorders (Macrae & Tyler, 2014), and the different theories on specific language impairments that attempt to discover the underlying causes of SLI (Evans, 2001; Gathercole & Baddeley, 1990; Tallal et al., 1996; Leonard, 1998), the further study of the types of SLI and influences of SLI on child development is warranted. In this chapter, we will be reviewing phonetic, phonological, syntactic, morphological, and pragmatic influences in expressive language impairment and example interventions designed for young children to improve their expressive language skills.

2. PHONETIC AND PHONOLOGICAL UNDERPINNINGS OF EXPRESSIVE LANGUAGE IMPAIRMENT

The terms phonetics, phonology, phonological processes, and phonemic awareness are inter-related (Carr, 2013). Phonetics is defined as the study of the nature, production, and perception of the sounds of speech, often without prior knowledge of the language being spoken (Matthews, 1997; Hawkins, 2003; Carr, 2013). More specifically, *phonetics* is the term for the description and classification of speech sounds, particularly how sounds are physically produced, transmitted and received (Hamann & Schmitz, 2005). English has 20 different vowels, and these vowels are all written by different combinations of 6 different letters, "a, e, i, o, u, y" (Hamann & Schmitz, 2005). For example, the orthographic spelling of a word (e.g., *please*) is different than the phonetic transcription that is placed between square brackets [pli:z]. Thus, the word *please* consists of three consonants, [p, l, z], and one vowel, [i:], and sounds are put between slashes (Hamann & Schmitz, 2005).

Phonology is defined as the study of the sound system of a language and the rules that govern the sound combinations (ASHA, 1993; Matthews, 1997; Carr, 2013). Thus, phonology is concerned with how sounds function in relation to each other in a language (Hamann & Schmitz, 2005). In other words, while phonetics is about physical aspects of the sounds in a language, phonology is about sound systems of a language, and phonetics is a descriptive tool necessary to study the phonological aspects of a language (Hamann & Schmitz, 2005; Clark, Yallop, & Fletcher, 2007). There are many examples to the study of phonology, since the organization of sounds can be accomplished in many ways (Clark et al., 2007). A *phoneme* is the smallest unit in the sound system of a language that can change the meaning of words; for example, the /t/ sound in the word *tile* differentiates it from the word *file* (Hamann & Schmitz, 2005). Another classification of sounds is the use of minimal pairs. *Minimal pairs* are two words with meanings that are dissimilar from each other but have the same sounds in the same place in each word, except for one different sound such as *cat/sat*, *pin/bin*, or *tub/hub* (Clark et al., 2007). Punctuation marks for phonemic and phonetic transcriptions of words differ. For example, while phonemically, the words *bead* and *bean* are transcribed as /bid/ and /bin/, phonetically, they are transcribed to be pronounced as [bid] and [bin] (Johnson, 2011).

Phonological processing is essential for a wide range of skills (Vandewalle, Boets, Ghesquiere, & Zink, 2012). It involves the representation, manipulation, short-term storage,

and retrieval of speech sounds (Snowling, 2000; Wagner & Torgesen, 1987). Beckman and Edwards (2000) characterized phonological development as a gradual accumulation of knowledge in the perceptual and articulatory domains. Phonological awareness refers to the knowledge that spoken words can be segmented into smaller abstract units (e.g., syllables, phonemes), and is assessed by various tasks that measure the ability to distinguish and manipulate these syllables or phonemes such as phoneme deletion tasks (Yopp, 1988; Wagner, Torgesen, & Rashotte, 1999). Phonological awareness is an important preliteracy skill and one of the best predictors of success in reading acquisition (Torgeson, Wagner, & Rashotte, 1994). It has been shown that children with phonological delay have significant difficulties in the completion of phonological awareness tasks, especially during preschool years (Bird, Bishop, & Freeman, 1995; Larrivee & Catts, 1999; Rvachew, Ohberg, Grawburg, & Heyding, 2003). These difficulties include but are not limited to tapping out the number of syllables or phonemes in a word (Webster & Plante, 1992), matching words that share an onset or rime (Bird et al., 1995; Rvachew et al., 2003), and deleting syllables or phonemes from words (Larrivee & Catts, 1999).

Several models have been developed that guided the study of phonological awareness (Swan & Goswami, 1997; Treiman & Zukowski, 1996). Swan and Goswami (1997) proposed that poor phonological awareness skills arise from deficiencies in both the precision of phonological specification of the underlying representations and the segmental organization of these representations. Treiman and Zukowski (1996) presented a developmental model for the study of phonological awareness skills. In their model, different aspects of phonological awareness develop at different phases within typically developing children. Initial ability is learning the skill to segment speech into words. This is followed by the ability to divide words into syllables, and then, to divide syllables into intrasyllabic components, and finally, intrasyllabic units into phonemes. The expectation is that segmentation at the syllable level will be easier than segmentation at the intrasyllabic level, which will, in turn, be easier than segmentation at the phoneme level (Treiman & Zukowski, 1996). This developmental trend was observed in a cross-sectional study within typically developing children, while it could not be confirmed in young children with SLI whose language abilities were followed from preschool to kindergarten and first grade (Thatcher, 2010). Children with SLI exhibited no significant improvement in their ability to segment at the various levels. It was argued that the generally decreased phonological awareness abilities may explain the lack of improvement in segmentation skills over time in children with SLI (Thatcher, 2010).

Earlier studies are in line with the arguments presented in Treiman and Zukowski's model (1996) such that a gradual increase in the amount of phonetic detail that is encoded in phonological representations occurs alongside developmental changes in the structure of these representations. Thus, children's representations become increasingly segmental in nature (Jusczyk, 1992; Nittrouer & Studdert-Kennedy, 1987). For example, Jusczyk (1992) has shown that infants perceive speech in terms of syllables rather than individual segments. Nittrouer and Studdert-Kennedy (1987) showed that 3- to 5-year-old children are more sensitive than adults to formant transitions when identifying fricative-vowel syllables. In contrast, adults attend more to the acoustic cues that are associated with the individual segments rather than to the syllable as a whole. With time, phonological representations are restructured to reflect a segmental ordering of individual phonemes, and children segment words into increasingly smaller units as they get older, starting with the word and syllable segmentation during preschool, progressing through onset-rime segmentation during

kindergarten, and ending with the segmentation of individual phonemes in grade school (Treiman & Zukowski, 1996). The child's gradually increasing perceptual knowledge about phonemes are linked to improvements in the accuracy and stability of articulation as the child adjusts his/her speech production to match the acoustic/phonetic characteristics of the native language speech-sound categories (Macken & Barton, 1980).

Developmental studies show that when toddlers begin to encode phonological representations of words in their lexicon, these phonological representations are lacking in phonetic detail (Werker, Fennell, Corcoran, & Stager, 2002). Children's ability to encode the fine phonetic detail of speech improves gradually, most likely as a consequence of repeated exposure to words and the challenging task of trying to organize their rapidly growing lexicon (Rvachew et al., 2004). For example, in a study with 3- to 7-year-old children and adults, both groups were asked to identify words that contrasted word-final stop consonants (Edwards, Fox, & Rogers, 2002). Results showed that preschoolers required more acoustic information than adults and older children to be able to recognize words accurately (Edwards et al., 2002). Findings from several studies supported the existence of a reciprocal relationship between perceptual encoding and vocabulary growth (Werker et al., 2002; Edwards et al., 2002). It was argued that the ability to encode fine phonetic detail permits the expansion of children's vocabulary, and in turn, the size and structure of the lexicon impacts the way in which speech is perceived (Edwards, Beckman, & Munson, 2004).

Children with SLI also exhibit novel word-learning deficits compared to their age-matched peers (Chen & Liu, 2014). Mandarin-speaking preschool children with SLI were exposed to novel words for unfamiliar objects, and word learning tasks included initial mapping and short-term repetitive learning (Chen & Liu, 2014). Results revealed that preschoolers with SLI performed as well as their age-peers in the initial form-meaning mapping task, while their word-learning difficulty was shown in the short-term repetitive learning task under a production demand, and their learning speed was slower than the control group (Chen & Liu, 2014). It was concluded that the word-learning difficulty in children with SLI occurred in the process of establishing a phonological representation, at the "beginning stage" of word learning (Chen & Liu, 2014).

In sum, phonetic skills and phonological knowledge are inextricably linked in development, and simultaneously implicated in children's language skills (Rvachew et al., 2004). Understanding the developmental progression of phonetic and phonological skills has research implications as well as clinical benefits (Rvachew et al., 2004).

3. THE INTERPLAY BETWEEN PHONOLOGY, MORPHOLOGY, PROSODY, SYNTAX, AND RELATIONS TO EXPRESSIVE LANGUAGE DEFICITS

Imprecise phonological representations (e.g., phonological representations of words) are associated with deficits in phonological awareness (Rvachew et al., 2004). It is proposed that the quality and precision of any given underlying representation will depend on children's access to a large set of stored exemplars (e.g., sufficient input), the ability of the children's auditory and linguistic systems to encode the acoustic/phonetic information contained in the input received, and the children's tendency to attend to and encode most relevant aspects of

that input (Rvachew et. al., 2004). While the interplay between phonetics, phonology, and phonological awareness is well established (Rvachew et. al., 2004), phonology is associated with other aspects of language that inform children's skills (e.g., morphology, prosody, syntax).

Inkelas (2014) reports that phonology and morphology are conceptualized as distinct modules, but they are constantly intermingled. In every language, at least some of the phonological patterns are conditioned by morphological factors and predicting the form of a morphologically complex word requires knowledge of the phonological rules of the language (Inkelas, 2014). Research has shown that studying the interplay between morphology and phonology demonstrates more about each phenomenon in relation to each other than studying them in isolation (Inkelas, 2014; Ajiboye, Dechaine, Gick, & Pulleyblank, 2011).

Morphological knowledge and awareness are intrinsically related constructs (Smith Gabig & Zaretsky, 2013). *Morphemes* are the smallest meaningful units in a language (Smith Gabig & Zaretsky, 2013). Morphological awareness is defined as the metalinguistic ability to recognize, reflect on, and manipulate the smaller meaningful parts of language such as prefixes (e.g., *re-*), base words/roots (e.g., *cycle*), and suffixes (e.g., *-ing*, *-ist*), to develop words that are morphologically complex (e.g., *recycle*, *cycling*, *recycling*, *cyclist*) (Wolter & Pike, 2015). The study of such sub-lexical word structures (i.e., roots, prefixes, suffixes) is the basis of morphological awareness (Smith Gabig & Zaretsky, 2013). Explicit morphological awareness is evident when individuals are able to analyze the word structures and word meaning, including the process of word formation and the semantic relationship among sub-lexical parts of words (Berninger, Abbot, Nagy, & Carlisle, 2010), the morpho-phonological properties of words influencing stress patterns and word pronunciation (Jarmulowicz & Hay, 2009), and a word's fit into syntactic frames (Stolz & Feldman, 1995). The weaknesses in morphological awareness appear consistent with the difficulties using the phonological information to decode (Kirk & Gillon, 2007). For example, Song, Sundara, and Demuth (2009) demonstrated phonological constraints on children's morphology. The results of their study provided strong support for the role of phonological complexity in explaining some of the variability in children's production of third person singular morpheme *-s* (Song et al. 2009). Findings showed that children produced third person singular morphemes more accurately in phonologically simple coda contexts as compared with complex coda (Song et al., 2009).

While the interrelationships between phonology and morphology inform language skills (Song et al., 2009), there are other key components involved in speech/language development. For example, prosody is an important concept to define and examine, since children use prosodic cues in their language production (Wagner & Watson, 2010). The acoustic-phonetic properties of an utterance that "vary independently of its lexical items" are characterized by the term "prosody" (Wagner & Watson, 2010). Acoustic realization of each acoustic-phonetic property has a perceptual and a temporal correlate (Kreiner & Eviatar, 2014). Fundamental frequency is perceived as pitch, and intensity is perceived as loudness, and prosody is defined as the patterns of variation in these properties (Kreiner & Eviatar, 2014). The term intonation refers to changes in pitch over a phrase, sentence, or utterance, such as the pitch-rise property of questions in English (Kreiner & Eviatar, 2014). More complex prosodic percepts, such as stress emphasis, pitch accenting, intonational breaks, and rhythmic patterns are generated by synchronized co-variation of various acoustic properties

(Kreiner & Eviatar, 2014). Thus, prosody refers to the structural patterns of acoustic variations over time (Kreiner & Eviatar, 2014).

Infants use prosodic cues as signals of different linguistic properties (Johnson & Jusczyk, 2001; Jusczyk et al., 1992; Speer & Ito, 2009). For example, Johnson and Jusczyk (2001) show that 8-month-old infants use stress patterns as a cue for segmenting the speech stream into words, and 9-month-olds prefer passages where the prosodic break corresponds to the major syntactic break in comparison to the passages where prosodic and syntactic breaks mismatch (Jusczyk et al., 1992). More specifically, infants use pre-linguistic prosodic cues as an organizational device that helps them to segment the continuous speech stream and notice different linguistic properties (Speer & Ito, 2009). Speer and Ito (2009) suggest that children use prosodic phrasal structure as a “proto-syntax” that serves as the basis for later language acquisition.

In older children and adults, prosody plays a central role in both comprehension and production of spoken language (Kreiner & Eviatar, 2014; Wagner & Watson, 2010). In production, most research has focused on the correspondence between prosodic boundaries and syntactic structures (Kreiner & Eviatar, 2014). For example, the number and positions of pauses in an utterance are roughly correlated with the number and positions of syntactic phrase boundaries (Selkirk, 1984) and the duration of pauses is correlated with the strength of the syntactic boundaries (Grosjean, Grosjean, & Lane, 1979). In a relatively recent review by Ladd (2008), the variety of different prosodic features that the speakers produced were associated with the boundaries and syntactic constituents (e.g., lengthening of the pre-boundary syllables, a “reset” of intonation to its base pitch) (Byrd, Krivokapic, & Lee, 2006; de Pijper & Sanderman, 1994). The rich and complex array of prosodic cues signal different aspects of syntactic structure, while also facilitating cognitive processing involved in language processing (Kreiner & Eviatar, 2014). Prosodic representation serves as a multi-layered map indexing items across different representations (i.e., phonological, syntactic, semantic), while the utterance is being processed (Frazier, Carlson, & Clifton, 2006).

In addition to phonology, morphology, and the use of prosodic cues, syntactic abilities inform children’s expressive language skills (Contemori & Garraffa, 2010). For example, in the context of morphology, syntactic knowledge assumes the understanding of the grammatical role of affix when assigning word meaning (Nunes & Bryant, 2006). As children gain more experience with complex words containing derivational and/or grammatical affixes, they acquire faster recognition and more nuanced understanding of the different morpheme types, and their grammatical functions (Smith Gabig & Zaretsky, 2013).

Sentence construction is a more advanced grammatical skill (Contemori & Garraffa, 2010). Several studies have described difficulties with respect to producing syntactically complex sentences that the children with SLI experience (Contemori & Garraffa, 2010; Hakansson & Hansson, 2000; Jakubowicz, 2003). For example, in a study with preschool children with SLI (ages 4 to 6), the children’s comprehension ability was found to be comparable to age-matched peers, while their production showed a wider range of variation, and the preschoolers with SLI were unable to construct any relative clause (Contemori & Garraffa, 2010). Jakubowicz (2003) found that like typically developing children, children with SLI had longer response times in comprehension tasks when the determiner-noun or the subject-verb agreement was incorrect. However, production tasks showed that children with SLI made verb tense omissions (around 25% of the time), not observed in typically developing controls (Jakubowicz, 2003). It was concluded that children with SLI are sensitive

to violations in comprehension just like the typically developing children, while they exhibit difficulties with production unlike their typically developing peers (Jakubowicz, 2003). In an earlier study by Hakansson and Hansson (2000), the comprehension and production abilities of young children with SLI (ages 4 to 6) with a main expressive language impairment were longitudinally examined. Even though the performance of children with SLI and the control participants was comparable in the comprehension task, production by the two groups differed significantly at both Time 1 and Time 2 (Hakansson & Hansson, 2000).

Phonological, morphological, and syntactic abilities, and the use of prosodic cues are among the skill-sets needed for successful development of expressive language skills (Smith Gabig & Zaretsky, 2013). Several interventions exist that have been designed to treat difficulties in expressive language, including but not limited to the treatment of expressive phonological delays, and expressive vocabulary delays (Rvachew et al., 2004).

4. COMMONLY USED INTERVENTIONS TO TREAT EXPRESSIVE LANGUAGE IMPAIRMENT

4.1. Phonetic Perception and Phonological Processes

Different kinds of interventions have been shown to result in significant behavioral and neural gains in individuals with language-related deficits. For example, while the research literature is mixed regarding the benefits of FastForWord, several studies have shown the remedial gains of phonological training using this program, including improvements in auditory discrimination, phonic match, phonic word, understanding instructions, and grammatical structures and rules (Gillam et al., 2008; Strong, Torgerson, Torgerson, & Hulme, 2011; Ylinen & Kujala, 2015). Among other interventions used to treat children with phonological processing and phonemic awareness difficulties are Lindamood-Bell Programs (Bell, 2015), Lindamood Phoneme Sequencing Program for Reading, Spelling, and Speech (LIPS) (Lindamood & Lindamood, 2011), and Earobics, a powerful multisensory reading intervention for children attending Pre-K through 3rd grade (Houghton Mifflin Harcourt, 2014). Interventions conducted with individuals with SLI also showed strengthening of oscillatory brain activity (Heim, Keil, Choudhury, Friedman, & Benasich, 2013), and auditory cortical responses (Pihko et al., 2007; Stevens, Fanning, Coch, Sanders, & Neville, 2008).

Phonetic skills and phonological knowledge are interrelated and both associated with phonological disorders (Rvachew et al., 2004). This perspective provides a justification for situating the speech/language therapy practices at the intersection of phonetic and phonological skills (Rvachew et al., 2004). Stimulability has been used as an assessment strategy to evaluate whether a child can perform certain tasks given certain antecedents and supports, and the use of this assessment method has been established as a reliable predictor of phoneme acquisition in spontaneous speech (Miccio, Elbert, & Forrest, 1999). In addition, it has been shown that the use of phonetic placement to ensure stimulability for target phonemes improves the success of phonological interventions (Powell, Elbert, Miccio, Strike-Roussos, & Brasseur, 1998; Rvachew, Rafaat, & Martin, 1999).

Word-learning interventions may help develop children's expressive language abilities, since they provide them with a more established vocabulary set that can be used during

communication (Chen & Liu, 2014; Kelley, Goldstein, Spencer, & Sherman, 2015). In experiments that test fast-mapping in children with SLI, children are usually presented with novel words that are embedded in sentences within a certain context (e.g., a play session) in which novel objects are marked by these novel words. Children's ability to comprehend or produce the target words is then tested. During the comprehension tasks, children are usually asked to select the corresponding object when they hear the novel word stimuli (e.g., by the help of a picture or a real object) (Chen & Liu, 2014). To test children's production of the novel word, a word naming task is usually used (Chen & Liu, 2014).

In an earlier study, children with SLI were instructed to fast map one novel word, and results showed that preschoolers with SLI comprehended the single novel word as well as their age-matched peers, however, they produced fewer of the words' phonemes than children with typical language development (Dollaghan, 1987). This suggests that for children with SLI, the phonological representation of a novel word may be sufficient to distinguish the words from alternative options during the comprehension tasks (Dollaghan, 1987). However, in children with SLI, the stronger and more complete representation that is required to fulfill the production task is not usually established (Dollaghan, 1987).

Based on the clinical need, an instructional component was also established that was embedded within the vocabulary intervention programs (Chen & Liu, 2014). The word-learning process was examined with "supported learning contexts" (SLC) provided (Gray, 2005, 2006; Gray & Brinkley, 2011). SLC word-learning tasks involve more modeling, prompts, and feedback by adults after the fast-mapping tasks (Kiernan & Gray, 1998). Results from the studies that used the SLC paradigm showed that children with SLI performed more poorly than their age-matched counterparts at novel word comprehension and production beyond the initial fast-mapping stage, since, in general, they learned fewer words, and required more trials to achieve the learning criterion (Chen & Liu, 2014).

Another paradigm to investigate word-learning ability was named the "quick incidental learning" (QUIL) paradigm, developed by Rice, Buhr, and Nemeth (1990). In the QUIL paradigm, new words are used to replace common but general labels. For example, "conduit" replaces a word like "hose" in a garden story. The words are embedded in a sentence and presented in an animated story. Children watch the video without prior notice of the word-learning task. After the video, they are asked to select the corresponding picture from four pictures when presented with a target word to assess their comprehension of the new words. Similar to the typical fast mapping studies, QUIL studies test the initial form-meaning mapping ability. However, the QUIL paradigm emphasizes the incidental nature of the linguistic context of learning support (Rice, Buhr, & Oetting, 1992). Results of QUIL experiments showed that children with SLI retained significantly fewer words than typically developing children matched by chronological age or by mean length utterance (Rice et. al., 1990). More exposure to the new words is also necessary for children with SLI to perform comparably to their matched peers (Rice, Oetting, Marquis, Bode, & Pae, 1994).

Multi-intervention studies examined the relative influence of different interventions on children's phonemic awareness, speech sound production, and expressive language skills (Tyler, Gillon, Macrae, & Johnson, 2011; Law, Garrett, & Nye, 2004; Gierut, 1998; Gillon, 2000; Hesketh, Adams, Nightingale, & Hall, 2000). For example, in a study by Tyler et al. (2011), two interventions were implemented within a group of 3- to 5-year-old children with co-occurring speech sound disorders and language impairment from the U.S. and New Zealand. One experimental group received the *PA/SS intervention* (Gillon, 2005), which

involved *phoneme awareness and letter/sound knowledge, integrated with speech sound production*; and the other group received the *MS/SS intervention* (Tyler, Lewis, Haskill, & Tolbert, 2003), which involved a *morphosyntax intervention and a speech sound intervention*, provided in alternate weeks. The PA/SS did not target morphosyntax directly, and the MS/SS did not target phoneme awareness and letter-sound knowledge directly (Tyler et al., 2011). Children from matched pairs were randomly assigned to these treatments, delivered in 6-week blocks separated by a 6-week break. Phoneme awareness, speech sound production and oral language outcome scores were collected pre-treatment as well as after each treatment block (Tyler et al., 2011). Measures that assess phonological awareness included rhyme detection tasks, phoneme awareness tasks that target initial phoneme identity, phoneme blending and segmentation, and letter name and letter sound knowledge (Gillon, 2005). Measures of spoken language outcomes included finite morpheme composite and MLU (mean length of utterance) from spontaneous language samples (Tyler et al., 2011). Percent consonants correct and cluster accuracy tasks were primary speech change measures (Tyler et al., 2011). Both intervention groups made significant gains in all measures, with the exception of a morpheme measure only approaching significance (Tyler et al., 2011). Results showed the need for early intervention that integrates oral language and phoneme awareness/early literacy skills for children with multiple deficits (Tyler et al., 2011).

In sum, several phonetic and phonological interventions (Powell et al., 1998; Rvachew et al., 1999; Ylinen & Kujala, 2015), word learning interventions (Rice et al., 1990; Rice et al., 1992; Chen & Liu, 2014; Kelley et al., 2015), and mixed intervention methods that combine phoneme awareness, letter/sound knowledge, and speech sound production tasks (Tyler et al., 2011) have been developed to help children with SLI improve their expressive language skills. In addition, such interventions have been linked with strengthened brain activation in children with SLI (Heim et al., 2013; Pihko et al., 2007; Stevens et al., 2008).

4.2. Morphological and Syntactic Processes

Children with co-occurring phonological and morphosyntactic disorders comprise the largest segment of preschoolers with identified speech and language disorders (Broomfield, & Dodd, 2004; Conti-Ramsden & Botting, 1999). Using correct grammar is especially challenging for children with expressive language deficits (Leonard, Camarata, Pawlowska, Brown, & Camarata, 2006; Leonard, 1998). Different explanations have been given regarding the reasons why children have expressive grammar difficulties (Leonard, 1998; Gopnik, 1990). According to one view, acoustic features of grammatical morphology in English (e.g., shorter relative duration and/or low phonetic substance), when combined with limited processing capacity in the form of slower processing, make the grammatical features more difficult for children with SLI to acquire (Leonard, 1998). Leonard (1998) argued that part of the problem rests in the children's ability to derive the grammatical function of the morphology before the acoustic patterns are lost in memory. For example, preschool-age English speaking children with SLI were found to be limited in their use of grammatical morphemes that pertain to tense and agreement (Leonard, Camarata, Pawlowska, Brown, & Camarata, 2008; Leonard et al., 2006). In addition, in line with the competence-based theories of SLI, Gopnik (1990) proposed that the grammatical deficits seen in children with SLI are due to an inability to learn the underlying rules for marking grammatical tense.

Leonard (1998) argued that omissions of bound morphemes are a hallmark of SLI, while other studies suggested that this deficit pattern can change substantially with changes in extrinsic language contexts (Bishop, 1994; Evans, 1996; Evans & Craig, 1992). For example, Evans (1996) found that for some children with SLI, omissions of bound morphemes were not dispersed evenly throughout their language, but, occurred only at points in spontaneous speech discourse where processing demands were the greatest. In such conditions in which the processing demands are high, a child with SLI who has slower lexical access may spontaneously organize his or her speech by dropping extraneous “grammatical” information not critical to the intended meaning to meet the timing restrictions inherent in spontaneous speech production (Evans, 2001). This type of spontaneous adaptive response is also witnessed when children with SLI produce longer and more complex utterances when given increased response times (Evans, Kass, & Viele, 1997).

The effect of morphosyntactic intervention and its cross-domain influences on phonology were studied as part of a larger project by Tyler, Haskill, and Tolbert, 2002. Children who received the intervention made significant gains in morphosyntactic as well as phonological changes (Tyler et al., 2002). The hypothesis was that the morphosyntactic intervention, which focused specifically on finite morphemes (Haskill, Tyler, & Tolbert, 2001), resulted in phonological gains because of its indirect focus on segments in final cluster forms (Tyler et al., 2002). Research by Kirk and Gillon (2007) demonstrated that children with a history of speech impairment who had received preschool phonological awareness intervention showed stronger morphological awareness knowledge than did children who received early intervention focused on speech production alone.

In an earlier study by Lee and Ashmore (1983), receptive and expressive *wh* interrogative performance of language-delayed children was investigated. The formulation of *wh* questions requires three steps: 1) choosing the appropriate *wh* word, 2) placing the *wh* word at the beginning of the sentence, and 3) inserting the auxiliary and performing a reversal transformation (Cattell, 1969). Typically developing children master the majority of *wh* questions by age 4 (Brown, Cazden, & Bellugi-Klima, 1968; Lee & Ashmore, 1983). Within young children (ages 4 to 6 years) diagnosed with language impairment (i.e., twelve subjects exhibited primarily expressive delays, and eight subjects had both expressive and receptive language deficits), the results indicated that all the children performed better receptively than expressively (Lee & Ashmore, 1983). In general, the types of syntactical errors made by the language delayed children resembled those made by the typically developing children during the third stage of language acquisition (i.e., the insertion of the auxiliary and performance of a reversal transformation in the sentence) (Lee & Ashmore, 1983). This result suggested that the children in this study used the same rules for formulation of *wh* interrogatives (i.e., where, what, who, when, why, and how) as those of typically developing children in the early stages of language development. However, the language-delayed children performed a limited number of transformations in a sentence, as evidenced by the number of auxiliary and inversion errors in their sentence constructions (Lee & Ashmore, 1983). The conclusion was that language-delayed children developed the same order of acquisition and rules for questioning as typically developing children, but, at a slower rate (Lee & Ashmore, 1983). In a study by Rvachew et al. (2004), pre- and post-treatment assessment results showed that there is a relationship between phonemic perception and articulatory accuracy and between phonic perception and phonological awareness. However, their findings were consistent with Gillon’s (2002) conclusion that remediation of expressive phonological delay does not

automatically lead to attainment of age-appropriate phonological awareness skills (Rvachew et al., 2004).

Interventions designed to treat morphological difficulties are better developed if they take into account research and clinical findings that indicate that morphosyntactic and phonological skills are related (Kirk & Gillon, 2007; Haskill et al., 2001; Tyler et al., 2002). Morphosyntactic interventions on language are usually designed focusing on the morphophonemic interactions, particularly finite morphemes (Haskill et al., 2001). Interventions should also target acoustic features of grammatical morphology and the processing speed capacity of children with SLI, since slower processing makes grammatical understanding more challenging for children with SLI to master (Lee & Ashmore, 1983; Leonard, 1998).

5. IMPLICATIONS FOR SOCIAL COMMUNICATION, WRITTEN LANGUAGE, AND COMMON CORE CURRICULUM

Expressive language deficits are most often associated with social-communication and written communication skills in young children (Larkin, Williams, & Blaggan, 2013; Washington & Warr-Leeper, 2006; Wolter & Pike, 2015), which are both necessary for daily living tasks at home and school. In most states, the school curriculum follows the Common Core State Standards in English Language Arts and Literacy (CCSS/ELA), which is a codified set of learning and end-of-the-year achievement expectations for children and adolescents from Kindergarten through the 12th Grade (Smith Gabig & Zaretsky, 2013). In addition to written communication, expressive language skills are associated with other aspects of the Common Core such as language, reading, and literacy skills (Smith Gabig & Zaretsky, 2013).

5.1. Implications for Social Communication

A large body of intervention techniques have been developed to treat expressive language difficulties during speech and social communication, including but not limited to computerized and non-computerized interventions to treat speech production and expressive grammar, the use of speech/language therapy to aid social skills such as friendship making, interventions that concentrate on parent-child supportive interactions to promote children's conversational responsiveness (Washington, Warr-Leeper, & Thomas-Stonell, 2011; Law et al., 2004; Majorano & Lavelli, 2015), and interventions that are conducted in the school (Fantuzzo et al., 1995; O'Connor & Stagnitti, 2011; Nicolopoulou, Cortina, Ilgaz, Cates, & de Sa, 2015; Nicolopoulou, 2002).

5.1.1. Computer Assisted and Non-Computer Assisted Treatments of Expressive Language Deficits

Use of computers is a viable option for the remediation of agrammatical productions during speech (Cohen et al., 2005; Washington & Warr-Leeper, 2006). Benefits of computers in treatment for children with SLI have been well established (Washington et al., 2011;

Gillam et. al., 2008; Cohen et al., 2005). For example, a newly designed computer-assisted treatment, *My Sentence Builder*, has recently been used for the remediation of expressive-grammar deficits, thought to be associated with deficits in verbal working memory in children with SLI (Washington et al., 2011). Other techniques such as *Reduced Syntax Therapy (REST)* (Springer, Huber, Schlenck, & Schlenck, 2000) & Syntactic Slot-Filler Approach (Fokes, 1976) target accurate production of sentences to address agrammatism in young children. Washington et al., (2011) indicate that when addressing agrammatism in young children, compensatory options can be used by a) training the accurate production of simple sentences and b) monitoring for generalization and expansion into more complex sentences.

In addition to computer-assisted treatment (C-AT) that addresses expressive-grammar deficits in children with SLI (Gillam et al., 2008; Cohen et al., 2005), non-computer assisted treatment (nC-AT) of expressive-grammar deficits also facilitates gains in the use of targeted structures (Beeke, Wilkinson, & Maxim, 2003; Leonard et al., 2006, 2008). For example, the use of techniques such as *sentence break-down* (i.e., breaking the sentence down into component parts such as subject-verb-object, SVO) and *subsequent build-up* (i.e., producing the sentence in its entirety) may be helpful along with drill-play and emphatic stress to highlight missed or errorful grammatical morphemes.

5.1.2. Speech/Language Therapy as an Intervention Method to Treat Phonological Difficulties Involved in Expressive Language Deficits

Speech/language therapy is a commonly used method to treat expressive language delays (ASHA, 2007, 2010). There are more than 130,000 speech language pathologists (SLPs) in the United States, of which an estimated 28,000 provide therapy services within elementary schools (ASHA, 2010; Bureau of Labor Statistics, 2012). In year 2014, the percentages of students on school-based SLPs' monthly caseload by degree of communication impairment were reported as follows: 26% of the total caseload as having severe/profound impairment, 44% with moderate impairment, and 30% with mild impairment (ASHA, 2014). SLPs' workload involves providing direct language intervention services to students with language impairments (ASHA, 2014). High-quality language intervention is emphasized as an important component for enhancing language, literacy, academic and socio-emotional outcomes of students, and quality of language therapy is very closely tied to the time pressures that SLPs experience (Biancone, Farquharson, Justice, Schmitt, & Logan, 2014).

Traditional speech/language interventions are based on direct interaction between student/patient and therapist via a set of activities developed by the therapist (Saz et. al., 2009). For example, computer-aided speech/language therapy software has been a major focus since the 1990's (Saz et al., 2009). In the area of phonetics/phonology, some therapy approaches have traditionally focused on articulation production and others have been more phonological/language-based. Articulation approaches target each sound deviation and are often selected by the SLP when the child's errors are assumed to be motor-based. Phonological approaches target a group of sounds with similar error patterns, although the actual treatment of exemplars of the error pattern may target individual sounds. Phonological approaches are often selected in an effort to help the child internalize phonological rules and generalize these rules to other sounds within the pattern (ASHA, 2015). Both approaches might be used in therapy with the same student at different times or for different reasons (ASHA, 2015).

In addition to selecting appropriate targets for therapy, SLPs select treatment strategies based on the number of therapy goals to be addressed in each session and the manner in which these goals are implemented. A particular strategy may not be appropriate for all children and strategies may change throughout the course of intervention as the child's needs change (ASHA, 2015).

Speech and language therapy designed for the acquisition of the phonetic system of the language consists of sessions between the SLP and the student who produces different words and receives an evaluation of the correctness of the pronunciation by the therapist (Saz et. al., 2009). There are many traditional interventions to treat phonological difficulties, including but not limited to minimal pair therapy, core vocabulary approach, a cycles approach, and distinctive features approach (ASHA, 2015). For example, Minimal Pair Therapy for phonological processes (e.g., final consonant deletion “kni/knife” or fronting “tape/cape”) may be used to demonstrate children with phonological disorders that there is a contrast between their production of the word (i.e., “tup”) and the target word (i.e., “cup”). Speech/language therapy using minimal pairs also demonstrates that a word with a substituted phoneme forms a different word with a different meaning (Weiner, 1981).

A core vocabulary approach focuses on whole-word production and is used for children with inconsistent speech sound production who may be resistant to more traditional therapy approaches (ASHA, 2015). Vocabulary targets for practice are those that are used frequently as part of the child's functional communication system. A list of frequently used vocabulary words is developed (e.g., based on observation and teacher report), and a number of words from this list are selected each week for treatment. The student is taught his "best" word production, and the words are practiced until consistently produced (Dodd, Holm, Crosbie, & McIntosh, 2006).

Hodson's Cycles approach to treating phonological disorders contrasts the child's actual production with a minimal-pair word to facilitate understanding of the semantic difference between the two productions (Hodson, 2010). During each cycle, one or more phonological patterns are targeted. After each cycle has been completed, another cycle begins, targeting one or more different phonological patterns. Recycling of phonological patterns continues until the targeted patterns are present in the child's spontaneous speech (Hodson, 2010).

Distinctive feature therapy focuses on elements of phonemes that are lacking in a child's repertoire (e.g., frication, nasality, voicing, and place of articulation) and is typically used for children who primarily substitute one sound for another (ASHA, 2015). This approach uses tasks that compare the phonetic elements/features of the target sound with those of its substitution or some other sound contrasts. Patterns of features can be identified and targeted, and producing one contrast often generalizes to other sounds that share the targeted feature (Blache & Parsons, 1980; Blache, Parsons, & Humphreys, 1981). In addition, the application “Vocaliza” trains the phonological abilities of children while also introducing to them the semantics and syntax of the language with varied activities (Saz et. al., 2009).

Macrae and Tyler (2014) indicate that children with phonological difficulties who use atypical error patterns should be given priority for intervention, since it is not likely that their performance will normalize without it. Macrae and Tyler (2014) report that the same could be said for children with co-occurring SSD and language impairment who show more frequent use of omission error patterns, given their more compromised linguistic system and their risk of developing literacy disorders. They suggest alternating speech/language goals on a weekly basis with a therapy approach to target both deficits (Macrae & Tyler, 2014). The alternation

of goals will lead to superior gains and similar phonological gains in children with co-occurring speech and language deficits, in comparison with approaches that target each domain in blocks and both domains in the same session (Tyler et al., 2003).

Speech language therapy may also target pragmatic and social-communication skills (Lee & Ashmore, 1983). For example, therapeutic activities that teach appropriate *wh*-questioning are successful when they follow the order of interrogative development presented in three stages (i.e., choice of the appropriate *wh* word, placement of it in the beginning of the sentence, inclusion of the auxiliary and inversion of the subject and the verb) (Lee & Ashmore, 1983). Expressive language interventions, therefore, should take into account these transformations required for production of interrogative sentences (Lee & Ashmore, 1983). Verb selection is also important, since use of intransitive verbs during interrogative sentence construction that do not need a direct object to complete their meaning (e.g., come, go, run, sleep) is easier for young children and may lead to better comprehension (Lee & Ashmore, 1983). The importance of the variety of clinical services that SLPs provide is well documented, since students with language impairments are prone not only to having problems with language skills, but also are susceptible to difficulties in literacy (Catts et al., 2002), academic performance (Conti-Ramsden, Simkin, Knox, & Durkin, 2009), and social-emotional functioning (Sundheim & Voeller, 2004).

5.1.3. Intervention Methods that Include Parents, Teachers, and Schools in the Treatment of Expressive Language Deficits

Families are an important part of any intervention designed to treat children's expressive language difficulties (Majorano & Lavelli, 2015). In a study with Italian children with SLI (age range: 3;4-5;6) and two groups of age-matched typically developing children, mother-child shared book reading sessions were conducted and recorded (Majorano & Lavelli, 2015). Maternal utterances that included or were related to a sophisticated word (i.e., low-frequency word) were coded on the basis of a) informativeness, and b) scaffolding provided. Sophisticated vocabulary included both sophisticated words read from the book, and sophisticated words that were introduced into the book-reading conversation spontaneously by the mother (Majorano & Lavelli, 2015). In addition, child utterances were coded for complexity, and children's lexical development was assessed three months later. Results indicated that mothers of children with SLI produced a higher percentage of directly informative utterances with gestural scaffolding than did mothers of chronologically-age matched children. Only in the SLI group, these kind of utterances were significantly followed by child's extended utterances. Child's lexical development (production) was related to direct maternal informativeness in both the SLI- and chronologically-matched groups, and to gestural scaffolding only in the SLI group. On the whole, these findings suggested that mothers of children with SLI attune their language to their children's linguistic limitations and that the gestural quality of the interactive scaffolding is related to these children's conversational participation and their level of lexical progress (Majorano & Lavelli, 2015).

Interventions designed in the schools may also increase children's language skills (O'Connor & Stagnitti, 2011; Lantz, Nelson, & Loftin, 2004; Stagnitti, 2009; Nicolopoulou et al., 2015). In a study by O'Connor and Stagnitti (2011), children ages 5-to-8 with multiple disabilities that included developmental delay and Autism participated in a play intervention entitled "Learn to Play Program." Their pretend play, language, and social skills were compared to a group of control children participating in traditional classroom activities

(O'Connor & Stagnitti, 2011). Play skills were assessed by two instruments: 1) Child-initiated Pretend Play Assessment (ChIPPA), a norm-referenced play assessment for children ages 3-to-7 that measures the quality of a child's ability to engage in pretend play (Stagnitti, 2007), and 2) Penn Interactive Peer Play Scale (PIPPS), a 32-item rating scale of preschool children's interactive peer play competencies (Fantuzzo et al., 1995). Findings revealed that children who participated in the play intervention showed a significant decrease in play deficits, were less socially disruptive, and more socially connected to their peers, while both the experimental and the control group improved in their overall language skills measured by the Preschool Language Scale, fourth edition (Zimmerman, Steiner, & Pond, 2002). The PLS-4 includes two subscales, and an overall language skills score that is a combination of these two scales: the Auditory Comprehension Scale that is used to evaluate how much language a child understands, and the Expressive Communication Scale that is used to determine how well a child communicates with others (Zimmerman et al., 2002). This study supported the use of play intervention in improving children's play, behavior, language, and social skills (O'Connor & Stagnitti, 2011).

In a more recent study, story-telling and story-acting (i.e., STSA) were combined to create an intervention that was integrated as a regular component of a preschool curriculum (Nicolopoulou et al., 2015). The STSA was introduced in the experimental classrooms for the entire school year and the participants were low-income 3-to-4 year old preschool children. Participation in the STSA was associated with improvements in narrative comprehension, print and word awareness, pretend play abilities and reduced play disruption (Nicolopoulou et al., 2015). Within another sample of low-income preschoolers (ages 3-4), participation in STSA led to significant gains in a narrative production task, and improvements in scores on the Expressive Vocabulary Test (EVT) that measured a combination of vocabulary knowledge and vocabulary-related skills (Nicolopoulou, 2002).

Use of visual cues has been established as an effective method that increases children's language ability (Cunillera, Camara, Laine, & Rodriguez-Fornells, 2010). For example, during the implementation of the Learn to Play program, children were required to examine photos after a play session and communicate what they represented (O'Connor & Stagnitti, 2011). It was concluded that use of visual cues may have been a contributing factor to the improvement of language scores within children participating in the play intervention (O'Connor & Stagnitti, 2011).

Other effective oral language and literacy interventions have been developed to promote school readiness among at-risk young children (Kelley et al., 2015). Among these were shared book reading and language enhancement interventions, Tier 1 high-quality general education curriculum, Tier 2 high quality small group interventions, and intensive individualized Tier 3 interventions (Fuchs & Fuchs, 2006; Fischel & Landry, 2008; Lonigan, Shanahan, & Cunningham, 2009; Marulis & Neuman, 2010; Mol, Bus, & De Jong, 2009; Mol, Bus, De Jong, & Smeets, 2008). Marulis and Neuman (2010) concluded that only vocabulary interventions using explicit teaching strategies produce large intervention effects. In these interventions, words are presented with explicit instruction that includes child-friendly definitions and multiple examples and contexts to provide information about word meanings (Coyne, McCoach, Loftus, Zipoli, & Kapp, 2009; Justice, Meier, & Walpole, 2005). For example, participants of a small group storybook intervention entitled "*Story Friends*," in which vocabulary and question-answering lessons were embedded in a series of

storybooks, had significantly higher scores on measures of vocabulary than the comparison group which was exposed to the regular school curriculum (Kelley et al., 2015).

In sum, both the parents (e.g., via dyadic reading sessions with children) and the schools (e.g., via play-based, storybook reading-based, and/or narrative ability-based programs to improve vocabulary and expressive communication) can be included in intervention designs to treat children's expressive language difficulties (Majorano & Lavelli, 2015; O'Connor & Stagnitti, 2011; Kelley et al., 2015; Nicolopoulou et al., 2015; Nicolopoulou et al., 2002).

5.2. Implications for Written Language and Written Communication

Written language skills (e.g., spelling) are influenced by children's expressive language abilities and vocabulary knowledge (Larkin et al., 2013). Even when children's speech difficulties are resolved through early intervention, some will struggle to use linguistic information, such as morphological information, to accomplish spelling of complex words (Kirk & Gillon, 2007). For example, early intervention, implemented as young as at 3 and 4 years of age that facilitates phoneme awareness, letter knowledge, and early reading development was associated with positive growth in spelling morphologically complex words (Kirk & Gillon, 2007).

In a longitudinal study, lexical-semantic abilities, verbal-sequential processing and speech production abilities (at Time 1) of 7-year old Dutch children identified with SLI predicted word reading and spelling development seven months later (at Time 2) (Van Weerdenburg, Verhoeven, Bosman, & Van Balkom, 2011). Verbal-sequential processing was the strongest predictor for both word decoding and spelling (Van Weerdenburg et al., 2011). The important role of verbal-sequential processing in learning to decode and writing words was emphasized for children with SLI (Van Weerdenburg et al., 2011).

The ability to segment and blend units of language such as phonology (i.e., phonemic awareness) and comprehension of vocabulary have been indicated to be predictive of reading and writing success (National Reading Panel, 2000; Wolter & Pike, 2015). Research evidence shows that phonemic awareness, a very important metalinguistic skill, has explained large unique variances in reading and spelling abilities of early elementary grade students (Ehri et al., 2001; Manis, Doi, & Bhadha, 2000). In addition, vocabulary knowledge during reading is directly related to extraction of meaning to comprehend written text (Elleman, Lindo, Morphy, & Compton, 2009).

Phonemic awareness and vocabulary skills, however, are not the only factors that have an influence on reading and spelling skills (Wolter & Pike, 2015). Morphological awareness, another crucial metalinguistic skill, also explains additional and unique variance in elementary grade students' reading and spelling abilities (Wolter & Pike, 2015). Ability to segment and blend morphemic units predicted reading and spelling in elementary school children (Apel & Lawrence, 2011; Wolter & Green, 2013; Wolter, Wood, & D'zatko, 2009). The awareness of morpheme units can aid in word decoding (e.g., pronouncing /s/ and /h/ separately, versus the incorrect pronunciation of *-sh*, in the word *mishap*) as well as in spelling (e.g., correctly spelling *cars* with the final *-s* pronounced /z/ but spelled consistently with the plural *-s*) (Carlisle, 1995). Other findings indicated that inflectional morphemes tend to be omitted in the spelling attempts of children with SLI; for example, the target word

“*raced*” may be spelled as “*race*” (Silliman, Bahr, & Peters, 2006; Windsor, Scott, & Street, 2000).

Recent research has increasingly shown that implications of specific language impairment for classroom learning should include an understanding of spelling development in children (Larkin et al., 2013). Individual children with SLI experience significant difficulties with morphological awareness, phonological memory, and expressive language (Marchman, Wulfeck, & Weismer, 1999). In addition, many children with SLI seem to show global phonological awareness deficits which would inhibit their ability to grasp the early stages of spelling development (Claessen & Leita, 2012). Given the potential role of spoken language in spelling proficiency, and the range of oral language deficits seen in SLI, many studies have found children with a history of SLI to be at risk for later spelling difficulties (Stothard, Snowling, Bishop, Chipchase, & Kaplan, 1998).

5.3. Implications for Common-Core Curriculum

The Common Core State Standards in English Language Arts and Literacy (CCSS/ELA) encompasses four broad curriculum areas: Reading, writing, speaking and listening, and language (Smith Gabig & Zaretsky, 2013). The Language strand of CCSS/ELA standards further codifies expectations into three subareas: Conventions of standard English, knowledge of language, and vocabulary acquisition and use (Smith Gabig & Zaretsky, 2013). A major goal of the Common-Core curriculum is explicit teaching of morphological processing to children and adolescents in order to facilitate word reading, reading comprehension, vocabulary development, and spelling (Smith Gabig & Zaretsky, 2013). In addition, as part of the common core standards, teachers are in need to be knowledgeable about phonetic and phonological principles, since (1) the sound system is primary and the basis for the spelling system; (2) English pronunciation is hard to teach students who are not native speakers of English without knowledge of phonetic/phonological processes; (3) teaching of specific subjects (i.e., poetry) requires that teachers teach about rhyme, alliteration, assonance, and other poetic devices that manipulate sound; (4) knowledge of different accents and language variation is a crucial skills for teachers; (5) there is a tendency to “hear” the sounds of the English language through its spelling system, and phonetics/phonology provides a corrective to that that teachers should convey to students; and (6) phonetics and phonology provide systematic and well-founded understandings of the sound patterns of the language (Delahunty & Garvey, 2010; Common Core State Standards Initiative, 2015).

SUMMARY AND RECOMMENDATIONS

Children with SLI experience moderate to severe difficulties in the comprehension and production of language in the absence of cognitive, emotional, neurological, or social impairments (Tomblin et al., 1997). These difficulties range from deficits in vocabulary and word-finding, to impairments in morphology, syntax, pragmatics, nonverbal and verbal working memory, slower verbal and nonverbal processing, and deficits in speech perception (Bishop, 1997; Leonard, 1998; Evans, 2001). While there are competence and performance

accounts of SLI, more complex accounts suggest that language disorders, from an emergent perspective, are a manifestation of children's unique interactions with the environment (i.e., language input) (Evans, 2001). Phonetic abilities and phonological knowledge are inter-related, and are among children's skills that interact with their morphological and syntactic abilities, which collectively inform expressive language skills (Contemori & Garraffa, 2010; Rvachew et al., 2004).

The ultimate goal in the study of individuals with language disorders is to discover an effective course of treatment (Evans, 2001). Among intervention methods used to treat SLI, specifically, expressive language impairment, are computer-assisted as well as non-computer assisted therapeutic programs, word learning interventions, and speech/language therapy (ASHA, 2015; Cohen et al., 2005; Washington & Warr-Leeper, 2006; Washington et al., 2011; Chen & Liu, 2014; Kelley et al., 2015). In addition, environmental interventions such as provision of maternal support (e.g., direct information regarding the meaning of sophisticated, low-frequency words, accompanied by gestural scaffolding) and school-based interventions (e.g., play-based learning, storytelling) have been shown to be effective for promoting children's conversational responsiveness and lexical development, particularly with children with SLI with primarily expressive language deficits (Fantuzzo et al., 1995; Majorano & Lavelli, 2015).

Chapter 32

COARTICULATION

Veno Volenec*

Faculty of Humanities and Social Sciences, University of Zagreb, Zagreb, Croatia

ABSTRACT

One of the central issues in contemporary phonetics is that of coarticulation. Speech segments do not and cannot occur isolated in real speech. As elements of a multisegmental utterance in continuous speech, all segments have neighbors which exert a certain degree of influence upon them. The vast array of articulatory adaptations that occurs as a result of the influence of one phonetic structure on another is what constitutes coarticulation in its broadest sense. Because of its ubiquitous nature in continuous speech, coarticulation has been and continues to be a central research area in experimental and theoretical articulatory phonetics. Naturally then, any integral theory or model of speech production, and to a lesser degree speech perception, must account for coarticulation. In this chapter we provide a general introduction to coarticulation, to the techniques used to measure it, and to the major theoretical and experimental contributions in explaining the nature and principles that govern it. Depending on the theoretical approach, the definition and scope of coarticulation may vary significantly, thus we aim to review and assess some of the more influential models of coarticulation, which constitute a fundamental part of contemporary phonetics. Theories and models of coarticulation also have significant consequences on phonological theory, especially the phonology-phonetics interface. Modelling coarticulation is central to understanding how the categorical, timeless and context-independent units suggested by phonology and the gradual, dynamic and context-dependent characteristics of continuous speech are related to each other. Therefore, in this chapter we also explore the place of coarticulation in the phonology/phonetics dichotomy, relating coarticulation to what may in essence be viewed as its phonological counterpart – assimilation.

Keywords: phonetics, coarticulation, speech production, continuous speech, articulation

1. INTRODUCTION

Speech is a dynamic and continuously varying process. In normal speech, sounds do not occur in isolation, but rather as integral elements of a multisegmental utterance, ineluctably exerting influence on other adjacent elements within the utterance. Thus what is mentally a separable unit, call it a ‘segment’ or a ‘phoneme’, in real speech is realized as a continuous stream of articulatory movements. Each of these segments projects an articulatory requirement, a ‘target’ to be reached by the articulators. But in actuality these ideal targets are not necessarily reached, especially not in a uniform manner, for various reasons, perhaps most notably because one target is drawn off by having to quickly (within milliseconds) aim at the next one. The succession of these articulatory movements is seamlessly streamlined: during the production one articulatory movement (related to one segment), another movement (related to an adjacent segment) begins. This ubiquitous property of speech has an important corollary, namely that at any given time during the articulation of speech sounds, the vocal tract may be influenced by more than one articulatory movement (Farnetani – Recasens 2013: 316). So what mentally (or even orthographically) may be considered discrete elements, in speech occurs as the overlapping of articulatory movements. This phenomenon is one of the core properties of speech and is usually referred to as ‘coarticulation’. Its precise definition, however, is a matter of debate and ongoing research in phonetics, and, as will be shown (§3), vastly depends on the theoretical framework adopted.

Coarticulation is a universal property of speech, but only in the sense that at least some coarticulatory effects are present in all (studied) languages of the world (Laver 1994: 376). However, the types of coarticulatory effects, their scope, direction, timing and causes all vary significantly from language to language, and from speaker to speaker (Perkel 1986: 261). Nevertheless, it is possible to reduce this great variability to a manageable number of categories by classifying coarticulatory effects along certain general criteria (§2).

As a feature of the articulatory apparatus, coarticulation may be measured (§4). Various measuring and imaging techniques are at our disposal, such as electropalatography, ultrasound, magnetic resonance imaging, computed tomography, electromyography etc., all with certain advantages and drawbacks. These techniques may be applied in coarticulatory research in order to improve understanding of articulatory organization during speech and to gain insight into various movement strategies present in coarticulation.

Theories and models of coarticulation have significant consequences on phonological theory, especially the phonology-phonetics interface. Modelling coarticulation is central to understanding how the categorical, timeless and context-independent units suggested by phonology and the gradient, dynamic and context-dependent characteristics of continuous speech are related to each other (Harrington et al. 2013: 244). This relation is particularly evident in the relationship between coarticulation and what may in essence be viewed as its phonological counterpart – assimilation (§5).

We shall explore these various topics pertaining to coarticulation in turn.

2. GENERAL ACCOUNT OF COARTICULATION

There are many different and more or less compatible views of what ‘coarticulation’ is. While there is by no means total consensus, most definitions of coarticulation include either ideas about articulatory movements pertaining to different segments being somehow changed, adapted or blended, or ideas about different articulatory movements being relatively independent but overlapping in time.

The first set of ideas, where articulatory conflict is usually handled by averaging out the goals of the competing articulations (e.g., Kelso et al. 1986), may be considered an ‘adaptive’ approach to coarticulation, due to the fact that the form of a particular articulatory movement may be changed under the influence of adjacent movements. An explanation of coarticulation in such terms, therefore, may take this form:

Coarticulation is (...) to be regarded as a process whereby the properties of a segment are altered due to the influences exerted on it by neighboring segments (Hammarberg 1976: 576)

In co-articulation, there is a discernible degree of accommodation between articulatory features of a given string of adjacent segments (Laver 1994: 151)

Adjacent segments can show an articulatory ‘feature-sharing’ process at work as part of their accommodation to their occurrence in the particular context (op. cit.: 376)

The coordinatory phenomenon of accommodatory spreading of articulatory features has come to be known as co-articulation (op. cit.: 379)

In co-articulation, we can say that a setting finds its expression as an adjustment of the featural properties of one segment towards greater phonetics similarity to those of an adjacent segment (op. cit.: 397).

The second set of principles, where articulatory conflict is viewed as temporal overlapping of relatively independent articulatory movements, may be considered an ‘invariant’ approach to coarticulation, because in such a view articulatory movements remain stable, albeit somewhat masked by the onsets and offsets of adjacent articulations. A definition of coarticulation related to such an approach thus may take these forms:

Coarticulation refers to the fact that at any given point during an utterance, the influences of gestures associated with several adjacent or near-adjacent segments can generally be observed in the acoustic or articulatory patterns of speech (Fowler – Saltzman 1993: 173)

‘Coarticulation’ refers to the overlap of articulatory gestures associated with separate speech segments, and by extension to its acoustic effects (Keating 2003: 330)

(...) the movements of different articulators for the production of successive phonetic segments overlap in time and interact with one another: as a consequence, the vocal tract configuration at any point in time is influenced by more than one segment. This is what the term ‘coarticulation’ describes (Farnetani – Recasens 2013: 316)

In real speech articulations transition continuously from one to the next, with movements constantly overlapping, and sometimes conflicting. These various transitional processes fall under the rubric of coarticulation (Gick et al. 2013: 217).

These two approaches are complementary rather than mutually exclusive: accommodation between articulatory characteristics of segments may be viewed as a result of the overlapping of articulatory gestures needed to produce them, where ‘articulatory gesture’ is defined as “an actively controlled movement toward a presumed target configuration” (Recasens et al. 1997: 544). Some phoneticians use the term ‘coarticulation’ in a narrower and rather literal sense of simultaneous movement of two different articulators – as ‘co-production’, so to say (see §3.4 for elaboration). Under such a definition, for example, the lip rounding produced during the articulation of a consonant, anticipating the rounding of a following vowel (as in *saw* or *sue*), is coarticulation, but the adjustment of the tongue position for a velar consonant, anticipating the tongue posture for the following vowel, is not. This second kind of phenomenon may then be termed ‘adaptation’ or ‘accommodation’ (Clark et al. 2006: 86). Here we will adopt a wide perspective and consider both types of processes as coarticulation. Whatever the point of view may be, coarticulatory effects may be classified in terms of their direction, scope and articulators involved.

When it comes to direction, two types of coarticulation are distinguished, anticipatory and perseverative coarticulation. ‘Anticipatory coarticulation’ occurs when the articulation of a particular sound is affected by that of a later-occurring sound. Accordingly, in anticipatory coarticulation the articulatory gesture related to a particular sound begins during the production of one or more articulatory gestures that precede it. Its direction is sometimes (e.g., Ashby 2011: 152) depicted as ‘L ← R’, where ‘L’ and ‘R’ represent adjacent speech sounds, and ‘←’ means ‘is influencing’. Anticipatory coarticulation is also known under various different terms, such as ‘right-to-left’, ‘regressive’ or ‘forward’ coarticulation (Kent – Minifie 1977: 117; Lubker 1981: 129; Reetz – Jongman 2009: 39). An example can be found in the behavior of velar plosives [k] and [g] in English. Velar plosives become fronted when preceding front vowels, as in the word *ski*. Therefore, in anticipation of the upcoming front vowel [i], which requires a fronted tongue body, the tongue in [k] contacts the velum at a substantially more forward location. Conversely, when a velar plosive is adjacent to a back vowel such as [u], it becomes retracted, as in *cool*. The same holds for the velar plosive [g], in words such as *geek* or *forgive*, where the tongue body is fronted, and *goo* or *ghoul*, where the tongue body is retracted. In a narrow phonetic transcription, such fronting and retracting of the tongue body may be noted with corresponding diacritic marks: [s̟ki:] and [k̠^{hw}u:l̟]. The latter example shows another kind of anticipatory effect, namely labial coarticulation, indicated by the diacritic ‘^w’ in transcription. During production of the plosive [k], which is usually unrounded, the lips nevertheless make a rounding gesture, in anticipation of the upcoming articulatory gesture characteristic for the vowel [u]. Vowels can also show effects of anticipatory coarticulation. Thus a vowel preceding a nasal consonant becomes nasalized because the velar port starts opening during the vowel in anticipation the upcoming nasal. This effect can be observed in a myriad of examples such as *seen* [s̠i:n], *soon* [s^wũ:n] etc. It is important to point out that a single sound may be affected by several distinct coarticulatory effects at the same time, depending on the totality of articulatory properties of the affecting sound: [k̠^w] in *cool* shows two distinct coarticulatory effects, retraction and labialization, where retraction stems from the vowel’s backness property and labialization from its roundedness.

In ‘perseverative coarticulation’ the prolonged influence of a certain segment is exercised on one or more segments which follow it in a stream of speech. Accordingly, in perseverative coarticulation the articulatory gesture related to a particular sound is still being produced

while the gestures of following sounds are being initiated. Therefore, in preservative coarticulation a simple ‘L → R’ relation holds. This type of coarticulation is also known as ‘left-to-right’, ‘carry-over’, ‘progressive’, ‘retention’ or ‘backward’ coarticulation (Kent – Minifie 1977: 117; Lubker 1981: 128; Reetz – Jongman 2009: 39). The devoicing of approximants following voiceless aspirated plosives can be viewed as an instance of perseverative coarticulation, with the voicelessness of the initial plosive carrying over to the following approximant, as in *please* [p^hli:z]. The aforementioned cases of anticipatory tongue body fronting and retracting work in an opposite, perseverative, direction as well, as in *seek* [si:k̚] and *arc* [aḱ], respectively. It is important to mention that the designation of coarticulatory effects as anticipatory or perseverative depends strongly on the theoretical premise that at some level before the production of speech there is an underlying linear abstract segmental representation, what is usually called a ‘phonological representation’, where discrete precedence relations hold (Hardcastle 2006: 503; see Harris 2007: §6.2 for discussion, and Cairns – Raimy 2011 for a review of precedence relations in phonological representations). Otherwise, the directionality of such effects would be untenable, and perhaps even the entire concept of coarticulation depends on this theoretical position: “An intuitive concept of ‘segment’ underlies our recognition that there is a phenomenon of coarticulation requiring explanation” (Fowler 1980: 114).

Coarticulatory effects may also be classified in terms of segmental classes that influence each other, namely consonants (C) and vowels (V). Thus the so-called ‘V-to-C coarticulation’ refers to the influence of a vowel on a consonant, in either direction (Recasens 1982: 114; 2002: 2828), as shown in the example *cool* [k^{hw}u:l̪], where the vowel [u] influences the consonant [k]. Another type is ‘C-to-V coarticulation’, where the consonant exerts influence on an adjacent vowel, like in cases of vowel nasalization. A particularly interesting case is the transconsonantal ‘V-to-V coarticulation’, initially described by Öhman (1966, 1967). Öhman found that in sequences V₁CV₂, where C is a stop consonant, the values of second formant transitions of V₁C and CV₂ depend not only on C and the adjacent V, but also on the identity of the transconsonantal vowel. Such a finding indicates that vowels in these cases are produced continuously, that is, the production of VCV utterances does not involve three linearly ordered successive articulatory gestures but rather a longer diphthong-like gesture on which a shorter consonantal gesture is superimposed. Not surprisingly then, cases of vowel harmony are sometimes also described as transconsonantal V-to-V coarticulation (e.g., Gafos 1999: §4.1). The fourth possibility is the ‘C-to-C coarticulation’, in which one consonant influences another. Hardcastle (1985: 253) provides electropalatographic evidence of C-to-C coarticulation in the word *weakling*, where the articulatory gestures of consonants [k] and [l] are overlapped during the period of about 28 ms. During that time the tongue is in contact with both the velum (related to [k]) and the alveolar ridge (related to [l]).

Different types of coarticulatory effects can also be related to different articulators involved in their production. Thus Farnetani and Recasens (2013: 316–317) recognize four different articulators involved in different types of coarticulation: lips, tongue, velum and larynx. Coarticulatory effects pertaining to perturbation of the lips give rise to ‘labial coarticulation’ (Farnetani 1999). Lip rounding (marked with ‘w’) and lip spreading (unmarked in transcription), as in *zoom* [z^wu:m] and *keel* [k^hi:l̪] respectively, fall under this rubric. Tongue displacements along the high/low and front/back dimensions are the essence of ‘lingual coarticulation’ (Recasens 1999). The mentioned case from Hardcastle (1985), where the back tongue body position required for the articulation of [k] is, for a brief time, overlaid

by the front tongue body position of [l], is an example of lingual coarticulation. ‘Velar coarticulation’, sometimes dubbed ‘velopharyngeal’ (e.g., Chafcouloff – Marchal 1999: 69), consists of nasality effects caused by the lowering of the velum. Nasalization of vowels adjacent to nasal consonants is a type velopharyngeal coarticulation and it works both in anticipatory (e.g., *sang* [sæ̃:ŋ]) and perseverative (e.g., *can you* [kʰænjũ]) directions. Cases in which coarticulatory effects are related to vocal fold abduction and adduction, especially to the property of voicing, are known as ‘laryngeal’ or simply ‘voicing coarticulation’ (Hoole et al. 1999). The perseverative effect of approximant devoicing, as in *please* [pʰi:z], is a type of laryngeal coarticulation.

Coarticulation is a phenomenon that does not only include the interactions between strictly adjacent segments, but also interactions between segments farther apart. By counting either the number of segments through which coarticulatory effects are spread, or by measuring the duration of such effects, we can determine the ‘scope’ or ‘span’ of coarticulation. A number of empirical findings related to coarticulatory scope exist. Öhman (1966), investigating V-to-V coarticulation in VCV clusters in Swedish, Russian and English, found that coarticulatory effects are independent of syllable boundaries. Similarly, Lisker (1978: 133) states that “lip-rounding and nasalization are segmental features of English that refuse to be contained within their ‘proper’ segmental boundaries, as these are commonly placed”. Amerman et al. (1970) note that speakers may anticipate an open vowel by beginning to lower the jaw during preceding consonants. Likewise, according to Benguerel and Cowan (1974) lip protrusion may be evident several consonants in advance of the rounded vowel for which it is required. They went on to show that in French labial coarticulation can extend up to 6 segments in anticipatory direction (Benguerel – Cowan 1974). Not surprisingly then, Amerman and Daniloff (1977) have shown that when a speaker articulates a CCV sequence, the tongue body may begin to move towards the vowel even during the first consonant. Laver (1994: 381) concludes that “the segmental domain of coarticulatory settings tends to vary with the type of setting involved”. In other words, the coarticulatory span of influence is hierarchically related to the type of coarticulation involved. Lingual coarticulation can be transsegmental, as shown by Amerman and Daniloff (1977), but is usually contained within the domain of the syllable. Velar coarticulation can cross both syllable and word boundaries: Moll and Daniloff (1971) showed that in English the velum can lower in anticipation of a nasal consonant several segments earlier, across such boundaries, provided that the influenced segments are all sonorants. Labial coarticulation seems to have the longest potential scope. Apart from Benguerel’s and Cowan’s (1974) demonstration of anticipatory labial coarticulation in French, Lubker et al. (1975), using electromyography, showed that in Swedish lip-rounding can start up to 600 ms ahead of a rounded vowel.

Causes for coarticulatory effects are various and not completely understood. Ashby (2011: 151) surmises that the function of coarticulation is “to create a continuum – a stream of speech without gaps”. One usual and often repeated cause for coarticulatory effects, especially for its perseverative direction, is the inertness of the articulatory organs (Daniloff – Hammarberg 1973; Hammarberg 1976). So in perseverative coarticulation the offset of an articulatory gesture extends in time, impinging on the upcoming gesture, because the articulator itself is too inert to move fast enough to complete the gesture entirely, before the next one is initiated. Also, factors such as the anatomical connections between articulators, the elasticity of articulator tissues, and aerodynamic factors are sometimes cited (e.g., Ohala

1981: 112) as further constraining the actions of the vocal apparatus. However, such explanations clearly do not hold for anticipatory coarticulation. Studies of Daniloff and Moll (1968) on labial coarticulation and of Moll and Daniloff (1971) on velar coarticulation revealed that the lowering of the velum in anticipation of a nasal consonant and the rounding of lips in anticipation of a rounded vowel can start up to four segments before the influencing one. These patterns clearly indicate that anticipatory coarticulation cannot be the product of inertia. Rather, the initiation of an articulatory gesture ahead of its time is explained by several different claims, some of which are experimentally confirmed. For one, the anticipation of articulatory gestures may be a production strategy that enables the articulatory organs to move fast enough (despite their inherent inertia) to produce segments and syllables at the rate of normal or faster-paced speech. So for example Daniloff (1973) claims that the tongue tip – the fastest of the articulators controlled by muscles – can perform only about 8 closures per second. Nevertheless, we are able to produce from 12 to 18 segments per second in normal speech, and up to 13 syllables in maximally fast speech (Škarić 1991: 298). Secondly, anticipatory coarticulation may be viewed as part of a general human tendency towards economy of movement, which is in constant conflict with communicative needs, or as Lindbloom (1990: 403) puts it: “Speakers can, and typically do, tune their performance according to communicative and situational demands, controlling the interplay between production-oriented factors on the one hand, and output-oriented constraints on the other”. In this sense, anticipation of articulatory gestures arises in order to minimize the movement of the articulators. Third, at the cognitive level, anticipatory coarticulation can be seen as evidence of the tendency for the brain to execute movements that have been planned ahead of time (Hardcastle 2006: 503; but see Farnetani – Recasens 2013: 341 for a brief discussion). Fourth, there may also be some perceptual motivation for anticipatory coarticulation. Thus, as a result of anticipatory coarticulation, acoustic information on an upcoming segment is available to the listener before that segment is articulated, and this prior information may facilitate more accurate perception than would be the case if all acoustic cues were confined within the temporal boundaries of that segment (Kühnert – Nolan 1999: 9; Fowler 2005: 200; Harrington et al. 2013: 246–247).

3. THEORIES AND MODELS OF COARTICULATION

3.1. Background

The basic concept of coarticulation was recognized at least as early as Henry Sweet’s *A Handbook of Phonetics* (1877). There Sweet (1877: 56) acknowledges the fact that, although it is useful to study sounds in isolation (analysis), in real speech sounds do not occur in isolation, hence the need to study speech as a “stream of incessant change” (synthesis):

We have hitherto considered sounds from purely analytical point of view, that is, each sound has been considered by itself, as if it were a fixed, isolated element. But in language sounds are combined together to form sentences, and many sounds only occur in certain fixed combinations. Hence the necessity for synthesis as well as analysis. Analysis regards each sound as a fixed stationary point, synthesis as a momentary point in a stream of incessant change. Synthesis looks mainly at the beginning and end of each

sound, as the points where it is linked on to other sounds, while analysis concerns itself only with the middle of the fully developed sound (Sweet 1977: 56).

However, it wasn't until the 1930s that the term 'coarticulation' was devised, presumably in Menzerath's and De Lacerda's book *Koartikulation, Steuerung und Lautabgrenzung* (1933), and it took further 30 years for the term to become widespread in phonetics, after the publication of influential works such as Lehiste (1964), Öhman (1966, 1967) and Fant (1968). The pioneering studies also include – as accounted by Kühnert and Nolan (1999: 11–16), and Farnetani and Recasens (2013: §2.1) – the so-called 'overlapping innervation theory' by Joos (1948), where he proposed that phonetic segments influence each other in such a way that the neural command for each segment is an invariant wave "that waxes and wanes smoothly" and that "waves for successive phones overlap in time" (Joos 1948: 109).

During 1960s, in light of considerable experimental evidence, Lindblom (1963a; 1963b) devised his influential 'target undershoot model', where he posited that a string of phonetic segments is realized by a string of commands issued at a very fast rate; since the articulators' maximum speed is restricted by biomechanical properties, they usually do not complete a given response before the onset of the next command. Thus the articulators often fail to reach their targets (i.e., they 'undershoot') in attempt to respond to more than one articulatory command simultaneously, which is in Lindblom's view the essence of coarticulation. Articulatory timing was further elaborated by Kozhevnikov and Christovich (1965), within the framework of what Bladon and Al-Bamerni (1976) later dubbed 'the articulatory syllable model'. There, based on a battery of elaborate tests on Russian speakers, the temporal extent of anticipatory (labial) coarticulation was taken as an indication of the size of the articulatory syllable: all the articulatory actions connected with one articulatory syllable are supposed to start at its beginning. As was already mentioned, in the 1960s Öhman (1966, 1967) developed his 'VCV model of coarticulation'. His most important finding was that the in V_1CV_2 sequences vowels influence each other, so that from V_1 to V_2 one diphthongal articulatory gesture is realized, upon which a consonantal gesture is superimposed. Lindblom's and Öhman's models have an important commonality: both presuppose that at the level of motor commands, the instructions to the articulators are invariant. However, the difference is that for Öhman the presence of coarticulation results from the co-occurrence of vocalic and consonantal instructions, whereas for Lindblom it results from economy constraints tending to minimize articulator displacements.

An important insight into coarticulation of that time was Bladon's and Al-Bamerni's (1976) concept of 'coarticulatory resistance'. They hypothesized that each allophone has a different value of coarticulatory resistance to which a speech production mechanism has access. Thus coarticulatory effects are allowed to spread until they are inhibited by a high resistance specification of some segment. The resistance values themselves were supposed to be determined by universal, language-specific and speaker-specific factors.¹ However, Kent and Minifie (1977: 120) were critical of such explanations, remarking that coarticulatory

¹ They wrote of this principle as follows: "Antagonistic vocal tract adjustments apart, coarticulation is inhibited only by 'coarticulation resistance' (CR) at some point in the succession of speech events. Each extrinsic allophone (and indeed each boundary condition) is assigned a value for CR by rules which may in some instances be language particular and in others quasi-universal. The CR value could be represented as a numerical coefficient attaching to a phonetic feature, say (3 CR), along the lines proposed by Chomsky & Halle (1968) for all other phonetic specifications in the phonetic system" (Bladon – Al-Bamerni 1976: 149).

resistance values seem to be based on many different poorly understood and quite general factors.

A significantly different approach in the study of coarticulation was undertaken in the 1970s within a more phonologically oriented framework, namely within generative phonology of that time and its theory of distinctive features (Chomsky – Halle 1968). These early ‘feature-based’ or ‘feature-sharing’ models of coarticulation, such as Daniloff and Hammarberg (1973) and Hammarberg (1976), incorporated coarticulation within the phonological component of the grammar, despite Chomsky’s and Halle’s (1968: 295) earlier explicit banishment of coarticulation from the grammar. The basic idea of such feature-based models was that the phonetic representation, which is the end-point of the phonological derivation and the feature-spreading process, and which serves as an input into the speech mechanism, necessarily includes both articulatory and coarticulatory specifications. Because the various features are not always specified for all given input units, the model is equipped with a look-ahead operator that scans the forthcoming units to determine the next specified value of a feature. For this reason, such models are dubbed ‘look-ahead models of coarticulation’. Coarticulation then, following instructions of from the grammar, smoothes out the differences between adjacent sounds so that the transitions between them are minimized. Such approaches, however, ran into a myriad of contradictory data, most notably its failure to predict the extensive nature of perseverative coarticulation in VCVCV sequences (Recasens 1989), and its inadequacy in dealing with contradictory underlying feature specifications for two different segments (Sussman – Westbury 1981). Therefore, feature-based models were forsaken for a time, until their revival in the late 1980s and 1990s.

From these developments three approaches to coarticulation emerged in more recent times. On one front Lindblom (1983; 1989; 1990) continued to develop the view in which coarticulation is a matter of speech economy and adaptive variability (§3.2); on the other front Keating (1985; 1988; 1990a; 1990b), in her ‘window model’, revived the feature-based approach to coarticulation; the third approach, developed jointly by Fowler (1977; 1980; 1985), Browman and Goldstein (1986; 1989; 1992), Recasens (2002) and others, sees coarticulation as a coproduction process to which articulatory gestures are the input. These three approaches, roughly speaking, comprise the contemporary theories and models of coarticulation.²

3.2. Speech Economy Theory

Speech, the optimal form of human communication, seems to be torn between two antagonistic tendencies: the successful relaying of information and the economy of effort in doing so. As a consequence of this simple truism, speech production is never an invariant process; it is always the resolution of the interaction between the listener-oriented requirements of successful communication and the speaker-oriented requirement of speech economy. Lindblom (1983; 1989) noticed this ever-changing equilibrium and termed it

² The distinction between a theory and a model, within coarticulatory research, is explained clearly by Farnetani and Recasens (1999: 31): „The aim of coarticulation theories is to explain coarticulation, i.e. account for its origin, nature and function, while coarticulation models are expected to predict the details of the process bridging the invariant and discrete units of representation to articulation and acoustics. Coarticulation theories are also expected to explain how listeners overcome coarticulatory variability and recover the underlying message”.

‘adaptive variability’: depending on situation and intent, speakers adapt their speech production to meet either of the requirements to a higher degree. So when a situation demands a high degree of phonetic precision (and thus more perceptual contrast), speakers are able to over-articulate; when this is not the case (e.g., in casual and informal speech), speakers turn to economy principles and under-articulate. This continuum of possibilities is termed ‘hyper-’ and ‘hypo-speech’, the first being the tendency to over-articulate, and the second to under-articulate (Lindblom 1990). Coarticulation plays a central role in such a theory because going from hyper-speech to hypo-speech the degree of perceptual contrast decreases, while the degree of coarticulation increases. Therefore, within the theory of speech economy coarticulation is seen as an instantiation of the hypo-speech principle: the tendency to economize articulatory movements and to propagate low-cost motor behavior.

Within this theoretical framework, a revised version of Lindblom’s target undershoot model was embedded. In the original work (Lindblom 1963a), coarticulatory effects were seen as resulting from the inability of the motor system to respond to articulatory commands issued in very short temporal intervals. The faster the speech production, the greater the extent of undershoot and reduction. The revised model (Moon – Lindblom 1994) was enriched with considerations of speech style. In this view, speech rate and coarticulatory effects are still proportionately related, but it is also shown that a deliberately clear style of speaking inhibits the degree of undershoot, despite the relatively high speech rate. This finding is consistent with the speech economy theory in that it presupposes that a clear speech style leads to a higher degree of perceptual contrast (leaning towards hyper-speech) and therefore entails less pronounced coarticulatory effects, while spontaneous speech style (leaning towards hypo-speech) adheres to economy principles and therefore entails more coarticulation. All in all, a low-cost strategy, characterized by prominent coarticulatory effects, is the norm in natural speech (Lindblom 1975).

Figure 1. Schematic representation of locus equations for maximal and minimal C-to-V coarticulation.

An important property of these findings is that coarticulation can be measured in statistical terms, namely by the so-called ‘locus equations’. A locus equation can be defined as “a straight-line regression fit to coordinates formed by plotting onsets of F2 transitions in relation to their coarticulated F2 midpoint ‘target frequencies’” (Sussman et al. 1993: 1256). In other words, each production of a CV syllable yields one datapoint consisting of an F2 value measured at vowel onset and an F2 value measured in the middle of the vowel. When all these points are plotted in an $F2_{\text{(onset)}}$ by $F2_{\text{(middle)}}$ space, a best-fitting line is drawn through this cloud of points such that each point is as close to this line as possible (*Figure 1*). The equation corresponds to a linear function ‘ $F2_{\text{(onset)}} = k F2_{\text{(middle)}} + c$ ’, where ‘ k ’ is the slope and ‘ c ’ is the intercept of the regression line. The more that a consonant is influenced by a vowel, the less the formant transitions converge to a common locus and the greater the slope in the plane of vowel onset frequency by vowel target frequency. Thus in coarticulatory research, locus equations can be considered as indicators of the degree of coarticulation between a consonant and a following sonorant (Reetz – Jongman 2009: 204).

Krull (1987; 1989) used locus equations to quantify coarticulatory effects in CV syllables. She showed that labial-consonant loci³ undergo larger coarticulatory effects than dental-consonant loci and that coarticulation is larger in spontaneous speech than in words read in isolation. Moreover, Krull (1989) found for CVC syllables that prevocalic stop consonants undergo stronger anticipatory vowel effects than postvocalic consonants undergo carryover vowel effects.

3.3. Window Model of Coarticulation

As reviewed in §3.1, feature-based models held that coarticulation is a part of the grammar, presumably a part of its phonological component. However, it was difficult to reconcile the fact that phonology, as conceived at that time (1970s), operates with discrete and time-independent elements with the fact that coarticulatory effects entail continuous processes distributed in space and time. In the second half of the 1980s, Keating (1985; 1988; 1990b) proposed a new feature-based model of coarticulation, called the ‘window model’. She agreed with the view that phonological rules cannot account for the gradual nature of coarticulation, but contested the assumption that coarticulatory effects are solely a result of extra-linguistic, biomechanical properties of the speech apparatus. Instead, in Keating’s view, coarticulation is governed by phonetic rules of the grammar.

The standard rule-based approach to phonology, as laid out in Chomsky and Halle (1968), takes an underlying representation, either from the lexicon or from the output of the syntactic module, applies to it a set of ordered re-write rules, and thus derives the output representation. Both the underlying (phonological) and the output (phonetic) representation are specified in terms of binary features. Keating supplements this architecture with intermediate phonetic rules, presumably governing coarticulation, and localizes them after the domain of application of phonological rules.

³ A ‘locus frequency’, or simply ‘locus’, may generally be defined as the “apparent point of origin of the formant for each place of articulation” (Ladefoged – Johnson 2010: 199), the point of origin of the consonantal formants usually depending on the adjacent vowels.

The input to the phonetic rule domain is a potentially underspecified phonological representation. Thus every feature of every segment may be assigned either ‘+’, ‘–’ or ‘0’ as its value. The phonetic component of the grammar then interprets these features by assigning a ‘window’ to every feature of each segment. Windows serve as a conversion medium from categorical phonological elements to gradual phonetic elements. These windows represent all the possible physical (temporal and spatial) parameters a segment can take, i.e., the maximal range of variability within a segment. Specified features (‘+’ or ‘–’) are associated with narrow windows and allow for little contextual variation; unspecified features (‘0’) are associated with wide windows and allow for more variation. The exact width of a window is also determined for each language from information on the maximum amount of contextual variability observed in speech. This allows for all intermediate degrees between maximally narrow and maximally wide windows.

Windows pertaining to different segments are connected by interpolation functions, called ‘contours’. Contours represent actual articulator trajectories over time and are governed by principles of efficiency and minimal effort (and in that respect are in line with speech economy theory). In principle, the narrower the window for any feature, the greater the coarticulatory resistance. Narrow and displaced windows require more curvature of the contour, which results in less coarticulation (*Figure 2; b*). When the windows are wider and aligned, however, a relatively straight line can be interpolated, which suggests more coarticulation (*Figure 2; a*).

Figure 2. Window model of coarticulation.

In *Figure 2*, example (a) shows a VCV sequence, [apa], and its specification for the feature [low]. The consonant [p] is unspecified for that feature in the phonological representation (first row), and remains unspecified up to the phonetic level (second row). Because of its underspecification, the segment [p] is assigned a wide window, allowing greater contextual variability. Both vowels around [p] are specified as [+low], so they get a narrower window. Since [p] allows for greater variability, the most economical way to connect the three windows is by drawing a straight line through them. In articulatory terms, this translates to minimal adjustment of the relevant articulator (in this case the tongue body) during the production of [apa], and therefore to maximal coarticulation. Conversely, in example (b), the phonetic rule assigns a negative value (‘–’) to the phonologically unspecified

segment [s]. Because the segment is now phonetically specified, it gets a narrow window, and since the value is negative, the window is located at the bottom, misaligned with adjacent vowels. The most economical line that connects the three windows requires a lot of curvature. This translates to significant adjustment of the articulator during the production of [asa], and therefore minimal coarticulation.

Most of the research done within the window model of coarticulation aims to account for coarticulatory cross-language differences. Since in this model coarticulation is accounted for within the grammar, the differences in coarticulation between languages may originate either from phonology or from phonetics. So for example Cohn (1993), using the window model, reports different velar coarticulatory effects in English, where nasality is not phonemic, than in French, where nasality is phonemic. In nasalized English vowels, the shapes of the contours describe smooth trajectories from the (phonologically) non-nasal vowel to the nasal adjacent segment, suggesting the presence of velar coarticulatory effects that have a phonetic origin. However, vowel nasality is inherently phonological in French and is therefore categorical and not a result of phonetic coarticulatory effects. The plateau-like shape of the contour describing articulatory movement in French corroborates this claim.

Keating's model was not met with universal acclaim. Browman and Goldstein (1993: 53) criticized the disparity between phonological and phonetic (under)specification and the general lack of constrained interaction between those two domains. Manuel (1987; 1990) argued that the existence of coarticulatory cross-language differences does not automatically imply that coarticulation must be accounted for within the grammar, by showing that language-specific coarticulation patterns may be completely unrelated to phonological constraints. Furthermore, Liker et al. (2008: 185) showed that the window model does not correctly predict the effects of V-to-V lingual coarticulation, since different segments with the same specification for the feature [high] under experimental ultrasound investigation showed different coarticulatory resistance in the same intervocalic position.

3.4. Coproduction Theory

The main tenet of the 'coproduction theory' is that the basic phonological units and basic phonetic units are not categorically different (i.e., abstract and discrete vs. concrete and continuous), but instead virtually identical: in all cases those units are articulatory gestures. In other words, the assertion is that what a speaker implicitly knows about speech sounds (phonology) is not different from what a speaker uses during speech production (phonetics). From this hypothesis then follows that coarticulation is any occurrence of the overlapping of articulatory gestures. Such a theory had been put forward in works such as Fowler (1977; 1980; 1983; 1985), Bell-Berti and Harris (1981) and Fowler and Saltzman (1993).

The coproduction theory is motivated by the fact that the distinction between abstract and timeless phonological units and concrete phonetic units that are organized in time relies on the idea of 'extrinsic timing', which precludes the possibility of any coherent explanation of coarticulation. Extrinsic timing here is intended to mean that the externalization (via speech) of the phonological component of the grammar, which operates in time-independent units like segments, depends on some kind of 'translation' of these timeless units into a temporally organized set of (presumably completely different) units of speech, say gestures. However, since in this view time is excluded from the phonological representation, the spoken utterance

is given temporal coherence externally, from the process of actualization, which seems to suggest a significant dissociation between the phonological planning level (timeless) and its execution (timed) (Fowler 1980: 113, 117). The paradox that this leads to is that anticipatory coarticulation obviously includes some kind of planning and temporal distribution of articulatory gestures, but at the planning level time just does not exist, since phonological representations are timeless. To overcome this adversity, Fowler (1980: 122) proposes a theory of ‘internal timing’, where phonological representations also include the temporal dimension. Thus the proposed units of phonology are ‘articulatory gestures’: planned and linguistically significant actions of the structures of the vocal tract, serially ordered, context-independent and dynamical (Fowler – Saltzman 1993: 172). This theory became the core idea behind Articulatory Phonology of Browman and Goldstein (1986; 1989; 1992), which propounds the claim that “phonology is a set of relations among physically real events, a characterization of the systems and patterns that these events, the gestures, enter into” (Browman – Goldstein 1992: 23), where gestures “are basic units of contrast among lexical items as well as units of articulatory action” (*ibid.*) that “can be used to capture both categorical and gradient information” (*ibid.*).

The coproduction theory adopts the basic insights of internal timing and Articulatory Phonology, namely that the input to any model of coarticulation are the dynamical and invariant articulatory gestures. It is thus proposed that gestures are not modified when actualized in speech. The intrinsic temporal structure of the gestures allows them to overlap in time, so that they are not altered by the context, but rather ‘coproduced’ with it (*Figure 3*). ‘Coproduction’ then entails the temporal overlap of articulatory gestures and serves as an explanatory theory of coarticulation.

Figure 3. Coarticulation as coproduction of articulatory gestures (adapted from Fowler and Saltzman 1993: 184).

As can be seen from *Figure 3*, both anticipatory and perseverative effects are accounted for by the same principle of gestural overlap. The prominence of a gesture increases and decreases in time and so does its influence on the vocal tract (and by extension on the acoustic signal). The dashed vertical lines delimit the intervals in which a certain gesture is most prominent. During the waning of gesture A, the production of gesture B is initiated. The time from the initiation of gesture B to the time where it becomes more prominent than

gesture A represents the scope of anticipatory coarticulation, and the time between where gesture C becomes more prominent than gesture B and the time where the realization of gesture B is finished represents the scope of perseverative coarticulation. Logically then, the bigger the gestural overlap, the larger the coarticulatory effects, while the degree of gestural overlap is determined at the level of cognitive planning.

The most prominent model of coarticulation developed within the coproduction theory is the ‘degree of articulatory constraint (DAC) model’ (Recasens et al. 1997; Recasens – Pallarès 2001; Recasens 2002; 2014), which aims to predict the scope and direction of lingual coarticulation by taking into account the demands imposed on the tongue dorsum during speech production. Different degrees of articulatory constraint, called ‘DAC values’, are attributed to consonants and vowels based on the involvement of the tongue dorsum in forming a constriction in the vocal tract during their production (Recasens et al. 1997: 545). A minimal DAC value (= 1) is attributed to segments which do not require any movement of the tongue dorsum: e.g., bilabials [p, b, m], labiodentals [f, v], vowel [ə]. An intermediate DAC value (= 2) is assigned to segments for the production of which the tongue dorsum is not directly involved in closure or constriction formation but is somewhat constrained by movements of the primary articulator: e.g., alveolars [t, d, n, s], low vowel [a] etc. A maximal DAC value (= 3) is assigned to segments primarily articulated by the tongue dorsum: e.g., alveolopalatals [ʃ, ʒ], palatals [j, ɲ, ʎ], velars [k, g, x], high vowel [i]. In other words, the more prominent and precise the requirements on the tongue dorsum during the formation of the constriction, the more the segments are constrained, while less constrained segments impose less strict requirements on the tongue dorsum. The concepts of ‘coarticulatory resistance’ and ‘coarticulatory dominance’ follow logically from this: a more constrained segment (higher DAC value) is more resistant to coarticulatory effects and exerts more prominent coarticulatory effects on adjacent phonetic segments, while a less constrained segment (lower DAC value) is less sensitive and less dominant in this respect (Recasens – Pallarès 2001: 274). A great deal of experimental data has been gathered using the DAC model, such as investigation of the relationship between coarticulation, assimilation and blending (Recasens – Pallarès 2001), studies of coarticulatory direction (Recasens 2002), scope of coarticulation (Recasens et al. 1997), coarticulatory resistance (Fowler – Brancazio 2000; Zharkova 2007), the relation of coarticulation and sound change in Romance languages (Recasens 2014) etc. An obvious limitation of the model is its applicability to effects regarding only lingual coarticulation.

4. MEASURING COARTICULATION

Precise data on various coarticulatory effects can be gathered by measuring certain parts of the vocal apparatus during speech. These measurements may be either ‘direct’ or ‘indirect’. Direct measurements come from instruments that are in contact with the measured structure (e.g., electropalatography), while indirect measurements come from instruments that are remote from the structures of interest (e.g., imaging techniques) (Stone 2013: 9). While many different techniques may be used for obtaining data relevant to coarticulation, three procedures are used frequently: imaging techniques (especially ultrasound), electropalatography and electromyography.

4.1. Imaging Techniques

Imaging techniques register internal movements without directly contacting the structures. An obvious advantage of such techniques is that they are noninvasive and unobtrusive, not impinging upon normal speech production. Also, they provide an image of the entire structure (such as the tongue), rather than single points on the structure. The four common imaging methods in research of speech production are X-ray, computed tomography (CT), magnetic resonance imaging (MRI) and ultrasound. Of these, the ultrasound has proven to be the most productive method in research of coarticulation.

In a lateral X-ray image, an X-ray beam (a ray of light with the wavelength ranging from 0.01 to 10 nanometers) is projected on one side of the head. The rays then pass through all the tissue in the head and are recorded as an image on a plate on the other side. In X-ray, soft tissue structures like the tongue are often obscured by harder structures like the jaw and teeth. Another, more significant drawback is that potential radiation hazards from long-term exposure to X-ray beams preclude the possibility of more extensive measuring. Although X-ray has played an important part in research of speech production (e.g., Kent 1972), it was seldom used in coarticulatory research due to its very low temporal resolution. A notable case is Wood (1996), who used X-ray to elucidate the differences between palatalization and coarticulation in Bulgarian, and to show that gestural programming for this case of palatalization is better described as coproduction of gestures than as feature spreading.

Computed tomography (CT) also uses X-rays, but in a significantly different manner: it records ‘slices’ of tissue as thin as 0,5 mm. A CT scan can image soft tissue more clearly than X-ray because the scanner rotates around the body taking multiple images, from different angles, of a single section of the body, and then creates a composite image. However, a CT still uses X-ray beams, so radiation exposure is still an issue. The temporal resolution is somewhat faster – about 15 images per seconds – but still not fast enough to provide for real time speech research, therefore it is also rarely an instrument of choice to phoneticians.

Magnetic Resonance Imaging (MRI) uses a magnetic field and radio waves to image a section of the tissue (see Stone 2013: 14–21 for a more detailed account of how MRI works). Numerous MRI procedures are available, such as high-resolution MRI, cine MRI, functional MRI etc., all using the same hardware, only in different ways. Although some phonetic research had been done using MRI (e.g., Story et al. 1996), very few investigations into coarticulation have actually used experimental MRI techniques (Stone 1999: 255), most likely due to its slow response time and low visual resolution. However, Kim (2012), using cine MRI, interpreted Korean palatalization as a gradual phonetic phenomenon, i.e., a type of V-to-V coarticulation, rather than a common phonological process involving consonants and front vowels.

Ultrasound produces an image by using reflective properties of sound waves (Stone 1999: 252). A sound wave (1 MHz frequency or higher) is emitted from the ultrasound’s transducer; it travels through soft tissue, and reflects back when it reaches an interface with a structure of different density, like bone or air. The reflected echoes are received by the transducer, processed by computer and displayed as a video image. By placing the probe under the chin (stabilizing it either by hand or by an immobilization kit), a clear image of the tongue body (contour of its outer rim) is acquired (*Figure 4*), which is appropriate for phonetic research. The sampling rate of fastest ultrasounds is about 90 Hz, adequate for most lingual processes, but too slow for the study of real-time laryngeal phenomena. Thus ultrasound imaging is

usually constrained to research into lingual coarticulation. For example, Liker et al. (2008) used ultrasound to test the predictive capabilities of the window model versus the DAC model of coarticulation in accounting for lingual V-to-V coarticulation. Zharkova and Hewlett (2009) used ultrasound to measure lingual coarticulation in English and showed that the tongue contour during [t] adapts to the influence of the neighboring vowels approximately three times more than the tongue contour during [a] adapts to the influence of the neighboring consonants. Of all the imaging techniques used in research of coarticulation, the ultrasound seems to be the most productive one.

Figure 4. Ultrasound image of the tongue body, shown in the midsagittal plane. The image was taken by *Shimadzu SDU-450X* ultrasound system with the signal of 3.5 MHz and 10 cm imaging depth. The narrow bottom part of the picture is where the transducer is pressed against the soft tissue beneath the chin. The white curved line is the interface between the tongue (beneath the white line) and air (above the white line), therefore the white line represents the outer contour of the tongue body. To the left is the tongue tip, which is partially obscured by the transducer's arc; but even if the arc were extended to the left, the tip would not be completely visible because of the mandible.

4.2. Electropalatography

'Electropalatography' (EPG) is a technique used for recording the contact that the tongue makes with the hard palate during continuous speech (Gibbon – Nicholaidis 1999: 229). EPG is an invasive technique inasmuch that the measuring equipment enters the human body, but it is completely painless and impinges upon normal speech production minimally. It requires the construction of an artificial palate, molded to fit precisely the speaker's hard palate, that is layered with numerous individual electrodes (i.e., sensors) that register the tongue-palate contact. The electrodes conduct this signal through the wires that lead out of the mouth and to a computer which generates multiple images of the contact. There are approx. 60 scanning electrodes on an artificial palate (the exact number depends on the manufacturer) (Wrench 2007: 3), with the sampling rate up to 200 Hz (Stone 2013: 29). Because of its relatively fast

sampling rate and high spatial resolution, EPG has a long and rich history in phonetic research, starting with Hardcastle (1972), and was easily extended to research of coarticulation.

Figure 5. Electropalatographic image of pronunciation of the word actor (From Gibbon – Nicolaidis (1999) Palatography. In Hardcastle, W. J., Hewlett, N. (eds.) *Coarticulation – Theory, Data and Techniques*. 229–245. p. 235.).

Figure 5 shows an EPG image of pronunciation of the word *actor*. The sampling rate is 100 Hz, therefore the interval between individual frames is 10 ms. The frames are ordered in rows from left to right, with the alveolar region at the top and the velar region at the bottom. Tongue-palate contact is indicated by zeroes. The articulation of [k] starts at frame 289, where a complete closure at the velum can be observed. However, while the velar closure is still maintained, an alveolar closure related to [t] is also formed, around frame 301. Through frames 301 and 302 both closures are maintained for about 20 ms. Then from frame 303 the velar closure starts to release, while only the alveolar closure is maintained, up to frame 316. From there on, there is a rapid decrease in tongue-palate contact during production of schwa. Coarticulatory effects are most prominent during frames 301 and 302, where both a velar and an alveolar articulatory gesture are maintained for a brief time. However, anticipatory effects can also be observed: during complete velar closure, the onset of the alveolar gesture is building up, starting from around frame 294. After the start of the velar release (frame 303), the velar gesture gradually starts to wane, but still exerts its influence on the vocal tract for several frames, which implies perseverative coarticulation as well.

A great deal of research into coarticulation had been done using electropalatography. Without any attempt at exhaustiveness, we can cite such examples as Recasens' extensive work on lingual coarticulation (later within the DAC model) and studies of coarticulatory effects in particular languages, such as Hardcastle (1994; 1995) and Byrd (1996) for English, Kohler (1976) for German, Marchal (1988) for French, and Farnetani (1990) for Italian. Recasens (1990) used EPG data to show that vowels differ in coarticulatory resistance from

effects exerted by adjacent consonants: consonant-dependent effects were shown to be larger upon those articulatory regions which do not intervene in the formation of a vowel constriction, therefore those lingual regions which are not involved in the formation of a vocalic constriction are left freer to coarticulate than those which are actively involved. Recasens et al. (1998) revealed in VIV sequences more prominent C-to-V effects for the Catalan dark [ɫ] than for German clear [l], more so in the [i] context than in the [a] context, which is in agreement with the existence of high lingual requirements on the formation of two constriction places for dark [ɫ]. Electropalatographic insights into coarticulation remain to be a highly productive research avenue.

It is worth mentioning that EPG and ultrasound show complementary data: EPG shows the place on the palate in contact with the tongue, but without showing which part of the tongue was used to make that contact; ultrasound shows the shape and position of the tongue during articulation, but without showing its relation to the palate. The main drawback of EPG is that it requires a specific custom-made artificial palate for every different speaker, which makes mass data collecting an expensive endeavor.

4.3. Electromyography

‘Electromyography’ (EMG) is a technique for recording the changes in electrical activity within muscles (Hardcastle 1999: 270). EMG allows for the study of neuromuscular mechanisms that underlie the production of articulatory gestures during speech. The key part of the EMG system are the electrodes which detect ‘muscle action potentials’: the electrical activity accompanying muscle contraction. There are several types of electrodes, but those commonly used in phonetic research are either ‘hooked-wire’ or ‘surface’ electrodes. Hooked-wire electrodes are inserted into the body by a needle, after a local anesthetic has been applied. They record signals from individual ‘motor units’ (a single motor neuron and the group of muscle fibers which it innervates), identified as spikes in the electrical pattern, and are most useful for investigating muscles that are not close to the surface of the articulator, such as the *genioglossus* muscle of the tongue (Raphael et al. 2011: 288). Surface electrodes are used to study the response of the muscle as a whole, because they record the gross muscle activity from a large number of motor units. They are applied to an articulatory structure either by an adhesive substance or by suction (Harris et al. 1964; Allen – Lubker – Harrison 1972), and are useful for investigating muscles whose fibers are just below the skin, such as the *orbicularis oris* muscle of the lips.

Besides providing a measure of the strength of muscle contraction, EMG also provides temporal measures of muscle activity, such as the duration of muscle contractions and the relative timing of the activity of different muscles contributing to the movements of the structures used in speech production. The recording process is relatively straightforward: the electrodes register the electric potential and send the signal to a computer where it is displayed. The interpretation of the results is, however, much more complex, especially in terms of the functions of particular muscles and the resultant movements of speech organs: “It is extremely difficult to attribute a particular EMG output to a function in a given muscle and even more difficult to infer movement of a speech organ from such an output” (Hardcastle 1999: 273). A comprehensive introduction to recording and interpreting EMG signals is given by Loeb and Gans (1986).

How is data obtained by EMG relevant to a phonetician? Speech researchers want to know the relationship between the neuromuscular activity needed to produce speech sounds and the actual movement of particular speech organs that produced those sounds. Quite generally, EMG provides insight into the complex control mechanism used in speech production. It has been employed in the study of coarticulatory effects as well (see Farnetani 1999: 154–155 and Hardcastle 1999: 274 for extensive references). For example, Lubker and Gay (1982) used EMG to compare anticipatory labial coarticulation in Swedish and American English. They showed that the rounded vowels of Swedish were systematically produced with more extensive and more precise lip-protrusion movements than the rounded vowel of English, which suggests “that Swedish and American English speakers have learned different motor-programming goals” (Lubker – Gay 1982: 437). Boyce (1990) used EMG to compare patterns of protrusion movements for upper and lower lip for speakers of English and Turkish. They measured EMG activity in the orbicularis oris muscle and showed that Turkish speakers produce “plateau” patterns of movement rather than “trough” patterns, and unimodal rather than bimodal patterns of EMG activity, which suggests that “English and Turkish may have different modes of coarticulatory organization” (Boyce 1990: 2584).

The main drawbacks of hooked-wire electrodes is that they provide certain discomfort for the subjects which may affect the naturalness of their speech, and that specialist knowledge is needed for the insertion procedure, in order to avoid piercing any blood vessels. On the other hand, while surface electrodes are easy to apply and are non-invasive, their use is restricted to the investigation of superficial muscles such as the *orbicularis oris*, and there are substantial difficulties in attaching them onto moist intraoral surfaces.

5. COARTICULATION AND ASSIMILATION

In phonological literature ‘assimilation’ is usually defined as a phonological alternation in which two sounds become more alike (Lass 1984: 171; Zsiga 2013: 1919). This definition is, however, strikingly similar to any general definition of coarticulation (see §2), thus the question of the relation between these two phenomena naturally arises. Many different answers to this question have been proposed in the literature and here we will review some of them.

One simple explanation is offered by Laver (2001: 176):

(...) given the rate that segments follow each other in a stream of speech, (...) one segment may influence the articulatory characteristics of segments yet to be spoken, or be influenced by those that precede it. When such an influence crosses a word boundary, it is said to result in assimilation; when it is restricted to word-internal action, it is said to show coarticulation.

This explanation, however, is not quite consistent with concrete data. In Croatian, for example, voicing assimilation occurs automatically and invariably both within a single (tonic) word and within a phonological word (a tonic word plus a clitic) as shown in (1a–b), but is blocked between different phonological words (1c).

(1) Croatian voicing assimilation

- a Word internal
 - /s-broj-i-ti/ → [zbrojiti] 'add up'
 - /svat-b-a/ → [svadba] 'wedding'
 - /glad-k-a/ → [glatka] 'smooth' (fem.)
 - /vrab-ts-a/ → [vraptsa] 'sparrow' (gen. pl.)
- b Within a phonological word
 - /s drv-ima/ → [zdrvima] 'with wood'
 - /kod kute-e/ → [kotkutee] 'at home'
 - /grax bi/ → [graybi] 'beans would'
 - /slog tee/ → [sloktee] 'syllable will'
- c Between phonological words
 - /grax živi/ → [grax živi] 'beans live'
 - /slog pada/ → [slog pada] 'syllable falls'

Example (1), and many other such examples in different languages (see Zsiga 2013: 1921–1922 for Russian and Korean), shows that assimilation operates both word-internally and across word boundary, without any significant differences. This suggests that using the type of morpheme juncture as a criterion for distinguishing between assimilation and coarticulation is not more than an arbitrary decision.

Another explanation pertains to different types of transcription:

The general convention in phonetics is to term coarticulation anything that will only show up in narrow phonetic transcription, reserving the term assimilation for changes involving a complete change of target. Often, assimilations are so extreme that they can be recorded in a much broader transcription, a phonemic transcription (Ashby 2011: 152).

In this view, the relation between coarticulation and assimilation is a matter of magnitude of the change. When a change is significant enough to be recorded in a phonological transcription, it is an assimilation; otherwise it is coarticulation and it may only be evident in phonetic transcription. In other words, what counts as one of these processes depends on the availability of symbols to indicate it and on conventional judgements about its auditory or linguistic significance. What is a “significant” change in this case, and what “significant enough” generally means in phonology and phonetics, has no definitive answer (though see below) and directs any coherent contemplation of how this criterion might distinguish between assimilation and coarticulation straight into the fundamental question of the relation between phonology and phonetics. Indeed, the matter of the relation between assimilation and coarticulation penetrates to the very core of long-standing dichotomies such as ‘phonetics and phonology’ (Beckman 1999), ‘gradient and categorical’ (Ernestus 2011), and perhaps ultimately ‘language and speech’, that is ‘*langue* and *parole*’ in structuralist terms (de Saussure 1959 [1916]: 9ff), ‘language competence and performance’ in traditional generative terms (Chomsky 1965: 4) and ‘I-language and E-language’ in more recent generative terms (Chomsky 1986: 22; 2013: 35). It has notably been argued that assimilation is a linguistic process pertaining to segmental phonological units, while coarticulation is a speech process pertaining to the gradual nature of phonetic elements (Chomsky and Halle 1968). As an extension of this view, the distinction between coarticulation and assimilation

may be delineated on theoretical grounds: phonology, being a certain kind of implicit knowledge, a part of language competence and therefore ontogenetically prior to phonetics, encapsulates assimilation entirely, and thus assimilation can be defined within it as an alternation (an unfaithful mapping of distinctive features) imposed upon an underlying representation and apparent at the level of a derived phonetic representation; conversely, coarticulation, belonging to the phonetic domain, occurs subsequently in language performance (namely, speech) and may be viewed as an extra-linguistic process. Thus assimilation in principle entails a change of at least one distinctive feature, whereby coarticulation entails articulatory adaptations that are grammatically (phonologically) insignificant, in no way pertaining to the system of distinctive features. Also, it is fairly well established that coarticulation to a large extent depends on factors unrelated to language (in the sense of mind-internal linguistic competence, the so-called 'I-language'), factors such as speaking style (Lindblom – Lindgren 1985) and speech rate (Hardcastle 1985). On the other hand, there seems to be no evidence that assimilation depends on any of these factors. However, this position is by no means universal and some influential theories contest most aspects of such an approach.

Attempts have been made (e.g., Hammarberg 1976; 1982; Keating 1990b) to integrate all that coarticulation stands for into the grammar, presumably into its phonological component, and to describe and explain coarticulation with the same atoms of representation used to model assimilation, namely with distinctive features. Keating (1990b) divides the phonological component of the grammar into phonological and phonetic parts, the former part consisting of phonological rules and representations, and the latter part, applying on the output of the former part, consisting of phonetic rules and representations.⁴ In this view, any kind of feature-sharing process between segments is coarticulation, and the type of rules that govern this feature-sharing process determines whether coarticulation is phonological (i.e., assimilation) or phonetic:

Phonological rules of feature-spreading will produce partial or complete overlapping of segments, including assimilation over long spans. Phonological rules nonetheless have only limited access to segment-internal events. Phonetic rules, on the other hand, can (and more typically will) affect portions of segments, or affect them only slightly, or cause them to vary continuously in quality (Keating 1990b: 452).

Contrary to this position, the theory of Articulatory Phonology (see §3.4) argues that assimilation can be accounted for in terms of differences in articulatory organization and gestural overlap, without invoking any phonological feature change. Browman and Goldstein (1990) showed that a coronal closing gesture is still present in English phrases which sound as though a coronal nasal had become labial: for example, in the phrase *seven plus*, the [n] is not changed from [coronal] to [labial], but is overlapped by the following [p], and [n] and [p] articulated together sound like [m], as in *se[vmp]lus*. Browman (1995) argues that apparently categorical assimilations are just endpoints of a gradient distribution and a total case of

⁴ "Phonological representations, which are essentially static and categorical, can be acted on by phonological rules, which change or rearrange the features which comprise segments. The output phonological representations can be acted on by phonetic rules, which interpret these features in time and space. Phonetic rules can thus, for example, assign a segment only a slight amount of some property, or assign an amount that changes over time during the segment" (Keating 1990b: 452).

gestural overlap. In other words, all assimilation is a kind of coarticulation. However, not all researchers agree that assimilation processes are describable in terms of gradual gestural overlap. Ladd and Scobbie (2003: 16) provide evidence that vowel assimilation at word boundaries in Sardinian is indeed categorical and conclude “that gestural overlap is on the whole not a suitable model of most of the assimilatory external sandhi phenomena in Sardinian, and that accounts of gestural overlap in some cases of English external sandhi cannot be carried over into all aspects of post-lexical phonology”.

Fowler (1990: §28.2) proposes a listener-oriented basis for discriminating between coarticulation and assimilation. When a listener perceives a sound change, i.e., when a sound change is “significant enough”,⁵ it is grammatically relevant, phonological, and therefore an assimilation. When a listener cannot be made to perceive a sound change, even though it can be proven to exist by instrumental measurement, the change is grammatically irrelevant, and therefore a coarticulation. Fowler (1990: 484) asserts that the “difference in listeners’ perceptions of coarticulation and assimilation reflects a real difference in the phenomena being described”, and remarks (op. cit.: 483) that “many processes identified as coarticulatory will count as nongrammatical, whereas true assimilations are grammatical”.

All in all, the theoretical and practical explorations of assimilation and coarticulation center around the question of whether these are two systematically different phenomena, related to different domains of the language faculty (i.e., to phonology and phonetics), or merely different instantiations of a single processes. In the first view assimilation is a part of phonology, and is therefore a mental process with results observable in the physical phonetic output,⁶ while coarticulation is a part of phonetics with no relevance for the language system. Alternatively, assimilation may be viewed as a type of coarticulation, perhaps as its endpoint, but with lines between them in practice mostly blurred, if present at all. The matter is far from being resolved and will indubitably motivate extensive further research.

CONCLUSION

It is not possible to delve as deeply as one would like into various aspects of coarticulation covered in this chapter, therefore we have attempted to counterbalance the resulting superficiality by citing some of the most influential literature. An indispensable source of information on coarticulation is provided in Hardcastle and Hewlett (1999) and Farnetani and Recasens (2013), and of course in the references cited therein.

One conclusion that can reasonably be maintained is that coarticulation is a universal characteristic of speech and this chapter has, hopefully, demonstrated that given real life speech – all articulation is coarticulation. We have attempted to provide some general ideas about what the term ‘coarticulation’ denotes and how it can be classified (§2). Various types of coarticulatory effects testify to the incredible complexity of speech production. Because of its ubiquitous nature in continuous speech, coarticulation continues to be a central research area in experimental and theoretical articulatory phonetics. A number of different theories and

⁵ “For example, no matter how hard we concentrate, we cannot make ourselves aware of the acoustic differences between the ‘intrinsic allophones’ (...) of /d/ in /di/ and /du/. (...) In contrast, we can be made aware of the durational differences between the vowels in *heat* and *heed*” (Fowler 1990: 483).

⁶ This position is in agreement with classic generative conceptions of phonology, namely that “all the work in phonology is internal to the mind/brain” (Chomsky 2012: 48).

models attempt to account for the nature and origins of coarticulation and to predict various aspects of its effects (§3). The theory of adaptive variability sees coarticulation as a consequence of speech economy. For models that have emanated from the theory of generative phonology, like the window model, coarticulation is a set of rules that converts categorical elements into gradual elements and serves as a link between language competence and performance. For coproduction theory coarticulation is the temporal overlap of articulatory gestures. The development of all these theories and models of coarticulation depends crucially on data provided by a number of different experimental methods (§4). These various techniques reflect the fact that contemporary phonetics is mainly an experimental science. Research into coarticulation also produces far-reaching implications for phonological theory and for the relationship between the mind-internal knowledge of language and its externalization through speech. These implications are particularly prominent in the complex relationship between assimilation and coarticulation (§5).

The existence of different and usually exclusive approaches to coarticulation and the fact that coarticulation remains a productive field of inquiry in phonetics permits us from arriving at specific and definitive conclusions. However, if one conclusion holds true universally, it is surely that “speaking is coarticulating gestures” (Farnetani – Recasens 2013: 320).

Beaumont Health, Physical Medicine and Rehabilitation,
Oakland University William Beaumont School of Medicine, MI, US

ABSTRACT

Velopharyngeal Insufficiency (VPI) is a disorder of resonance and speech which affect all individuals with cleft palate. VPI can occur with or without compensatory articulation errors. Several intervention methods have been reported for treating compensatory articulation errors in patients with cleft palate. Two of the most commonly used of these intervention modalities are a phonologic based intervention and a phonetic or articulatory intervention. Although both modalities have been reported as being effective, it seems that a phonologically based intervention can more readily enhance to carry over the adequate articulation placement into connected speech. The reason for this advantage is that phonology addresses not only the peripheral aspects of speech production but higher levels of linguistic organization. Thus, addressing compensatory articulation errors in a more linguistically based context, can usually be more effective for acquiring and using an adequate articulation placement during connected speech.

It is necessary to appropriately classify the severity of the compensatory articulation errors, with especial focus on the response to speech pathology intervention strategies. Also, the selection of phonologically based strategies to be used during the speech intervention, seem to enhance effectiveness of the specific strategies for correcting articulation placement.

This chapter addresses how an approach based on phonological principles can be a reliable method for the speech intervention in children with cleft palate and compensatory articulation errors. In this chapter, a categorically stratified scale for classifying compensatory articulation errors according to severity and response to therapy is

described. Finally, some strategies for speech intervention which are more suitable for a phonological and linguistic intervention are presented. The chapter explains how is that selecting the strategies to be used during the intervention according to the severity of the articulation errors seem to increase their effectiveness.

Keywords: speech, treatment, cleft palate, language

INTRODUCTION

Articulation disorders in children are typically considered to be either phonologic or phonetic in nature. Phonetic disorders are related with inadequate speech development with anatomic, physiologic and/or motor deficits. In other words, the abnormalities involve either voicing or articulation placement and manner. In contrast, phonologic disorders are considered to be linguistically based and they seem to be reflecting abnormal processing in the organization and representation of the phoneme system of the language. [1]

Several authors have described that children with cleft palate are at risk for phonetic based problems due to the abnormal vocal tract structure inherent to the cleft. One of the main valves of the vocal tract is entirely dysfunctional, the velopharyngeal sphincter (VS). However, children with cleft palate can be also at risk for phonologic disorders. That is, the problem is not only structural but it involves the development and establishment of the system of rules which regulates speech production. [2]

Speech disorders caused by a palatal cleft, which affects the development of the phonologic rules system occurring between 0 – 18 months of age, are in the end a consequence of the cleft. It has been reported that babbling and cooing during the first months of life are an important element for the appropriate elaboration of the phonologic rule system in the central nervous system. These vocal tract rudimentary movements for producing sounds are being produced in abnormal conditions, that is, in the presence of a defective velopharyngeal valve for regulating intraoral pressure and nasal resonance. The abnormal vocal tract movements secondary to the defective structure, in the initial stages of development, produce a phonetic based disorder. However, over time, these errors become incorporated into the developing phonologic rule system and the disorder becomes phonologic. [2, 3]

Phonology is a much broader concept than articulation. Phonology refers to the higher component that governs the manner in which speech sounds are patterned in order to produce speech. It involves the vast repertoire of phonemes that can be found in any language. In other words, the involvement of those sounds which function in the language for signaling a change in meaning. Phonology also involves alternations which are undergone by phonemes when they occur in different phonetic contexts and combinations of sounds that occur in language. [1, 2]

Speech intervention for a child with cleft palate using a phonetic or peripheral approach addresses learning articulation placement, voicing and manner as specific times of motor learning. Usually in a phonetic approach some strategies as the use of minimum pairs, intense repetition and a sequential approach going from syllables to words to sentences, focusing on phonemes in different positions (initial, middle and final) are used. Moreover, the errors in articulation are considered as disruptions at some level of the relatively peripheral articulatory

movements of the vocal tract. Therefore, some intervention procedures are based almost exclusively on the notion that the articulation deficits are caused by a faulty control of the articulators. In contrast, when a phonologic approach is used, children must learn more than just a set of complex articulatory patterns associated with words. They must learn a complete phonologic system. Furthermore, several reports describe that some central, cognitive-phonological processing must be included in any description of phonological acquisition. [2 - 5]

Children learn speech by gradually trying to approximate to the speech sounds that are being presented to them by the significant adults around them. In cases of cleft palate, besides the resonance and intraoral pressure deficits inherent to a cleft of the secondary palate, some children deviate in an aberrant developmental pathway. In an attempt to approximate to the production of some sounds but facing a great obstacle, that is, a Velopharyngeal Insufficiency (VPI) secondary to a palatal cleft, they start producing sounds which have no relationship with the meaningful sounds of language. Examples of these sounds are substitutions of glottal stops by plosive phonemes (/k/, /p/) or substitutions of pharyngeal fricatives by fricative phonemes (/s/, /sh/). These behaviors have been denominated compensatory articulation errors.

Approximately one third of patients with cleft palate present with compensatory errors. It has been reported that the prevalence of language disorder is higher in patients with compensatory articulation errors. Furthermore, since the nature of these errors involves the control of the vocal tract by the central nervous system, they persist even after the VPI has been corrected surgically. Compensatory articulation errors involve not only the vocal tract but higher levels of speech sound production. [6 – 10]

A phonologically based approach for treating compensatory articulation errors in patient with cleft palate does not necessarily rejects well established principles underlying traditional management of articulation disorders. In contrast, articulation must be recognized as a critical aspect of speech sound development under any theory. Consequently, phonological principles should be considered as adding new dimensions and a new perspective to an old problem, not simply as refuting established principles.

The purpose of this chapter is to describe and analyze two approaches for the speech intervention in children with cleft palate who present with compensatory articulation errors. The first approach is a phonetic or articulatory approach which addresses the articulation errors at the peripheral level. The second approach is based on phonological principles and considers that the compensatory articulation errors are linguistically based. Thus, in this latter approach, not only the motor – peripheral – structural aspects of articulation are addressed but higher levels of linguistic organization are also considered during the intervention.

PHONOLOGICALLY BASED INTERVENTION FOR CHILDREN WITH CLEFT PALATE AND COMPENSATORY ARTICULATION ERRORS

When Speech and Language Pathology intervention is based on phonological principles, some implications for the assessment and management of children with cleft palate may be assumed, including analysis of phonologic processes in addition to a more phonetic or peripheral articulatory assessment. Some scaffolding strategies have been described to be

used in the speech intervention for these children. These strategies are basically aimed to modify the system of speech sound production or articulation in each child. Using these strategies is useful for upgrading the child's communicative turns in order to increase speech and language performance. These strategies are helpful for assisting in the formulation of messages of increasing complexity, meaning specificity, accuracy and clarity of expression. Scaffolding strategies include prompts, questions, providing information, restatements, and other procedures, which provide a reliable support to the individual as he/she is actively engaged in the process of conveying a message. [11 - 13]

Several authors have described scaffolding strategies for facilitating and enhancing oral communication and/or articulate speech sounds. However, it is important to study the possible relationship between different stages of speech development or severity of articulation impairment, and the effectiveness of these strategies. Some of the most commonly used strategies include the following: Modeling, providing phonemic cues, use of minimal pairs, use of cycles, imitation, drills, requests for clarifications, phonetic changes and expansions, among others. [14 – 19]

SCALE FOR THE CLASSIFICATION OF THE SEVERITY OF COMPENSATORY ARTICULATION ERRORS

As mentioned herein, speech acquisition is gradual and it should be considered as a developmental process. By the same token, the correction of compensatory articulation errors has to go through diverse stages. A clinical scale of severity of the use of compensatory articulation errors in children with cleft palate has been previously described. [15, 18] This scale has been used for determining the stage of the process of correcting compensatory errors in which the child is at the time of the evaluation, that is, how severe are the errors in each child at a particular time. The scale mentioned herein is described as follows:

- Appropriate articulation. (First category) The child is able to produce adequate placement and manner of articulation during spontaneous speech, including non – present situations.
- Inconsistent articulation. (Second category) The child shows compensatory articulation errors inconsistently during spontaneous speech. Intelligibility is not significantly affected.
- Articulation within context. (Third category) The child self-corrects articulation when using speech within a specific context. For example during telling a story from a story book which the patient already knows well. Nonetheless he shows frequent compensatory errors during spontaneous speech, and this may affect intelligibility.
- Articulation with strategies. (Fourth category) The child can correct articulation during isolated words or selected short phrases, only when the clinician uses specific instructions on articulation. Intelligibility is affected.
- Articulation of isolated phonemes. (Fifth category) The child is able to correct articulation only in isolated phonemes through direct instruction. Intelligibility is severely affected.

- Constant CAD. (Sixth category) The child is not able to correct articulation not even in isolated phonemes and despite direct instruction. Intelligibility is severely affected.

It has been reported that some of the scaffolding strategies commonly used in speech pathology interventions for correcting compensatory articulation errors, can be more appropriate, depending on the degree of severity of compensatory errors in each child. [15, 18]

STRATEGIES

The following strategies are the most commonly used during speech pathology intervention in children with compensatory errors:

- A) Modeling: Modeling is one of the most frequently reported strategies. The speech pathologist models the speech and/or language behavior that the child is to learn. Some clinicians have reported that children respond spontaneously if the language behaviors being stressed are at the child's level. Thus, they model the behavior but do not normally request for formal elicitation. Modeling approaches the normal conditions of language learning more closely than the elicited imitation procedure. [20] Example: Child: “_all he_ (call her)”. Clinician: “Yes, call her”. This strategy has been often described as useful for language development, but it is also proposed as a strategy for children with articulation impairment, such as compensatory articulation errors. Hoffman states that the models of appropriate articulated words in context are thought to help stimulate appropriate syllabic and phonemic organization. [1] The clinician has the opportunity to model and talk about the structure of words within an overall communicative context.
- B) Modeling with stress: With this strategy, the speech pathologist models targeted sounds of speech, but includes a brief pause before the sound and also, a stress on the sounds (phonemes) the clinician wants to model. For example, during a play situation in which a cake is being cut, the child says “_ut the _ae_ (cut the cake); The clinician can respond “yes, (pause)...cut the (pause)...cake. I will (pause)...cut the (pause)...cake and give you a (pause)...piece”, stressing the targeted phonemes for the purpose of making them more easily audible and facilitating to focus attention on those specific sounds.
- C) Cloze procedure with phonemic cues: With this strategy, the clinician prompts the child's communicative turn by supplying part of the utterance and letting the child fill the rest [24]. If necessary, the clinician can provide the selected sound of the target word [12]. For example, when reading a storybook, the clinician can say: “Yes, she was hungry, and she found three bowls of ____ (soup) on the t t ____ (table)”. The idea is that sharing the responsibility of telling the story and letting fill in the blank space, the children can focus on the specific words and the targeted sounds. Also, using phonemic cues by providing the initial sound or syllable the child can direct his/her attention to the targeted sound and the distinctive features of it.

- D) **Phonetic changes:** The speech pathologist indicates that the message would be more easily interpreted with a modification in speech production [12]. For example, when the child says “the _en (the pen)” reading a storybook in which there are different objects, the clinician says: “the pen”. Remember to put your lips together and make an explosion: p p pen”. With this strategy, the information would directly contribute to refining the phonemic distinction being articulated.
- E) **Think aloud in phonemic awareness:** Originally, this is a metacognitive strategy where the speech pathologist verbalizes thoughts while reading a selection, thus modeling the process of comprehension. This strategy enables to demonstrate the patient how to select an appropriate articulation process at a specific point in a particular communicative message. The clinician verbalizes specific think-aloud about different levels of language organization including information about the sounds of speech. For example, before reading a storybook, the clinician says: “Let us think which sounds we will be focusing on. We have to consider that some sounds are short and explosive like /k/, /p/, /t/. I will write these letters for reminding us to use them while we refer to the ideas and words of the book. Besides, we have other sounds that are long and continuous: /s/ or /f/. I will write these letters in this other paper. While looking at the storybook, the clinician is focusing on the target sounds and explaining the characteristics of each phoneme and how changing the sound can change the characteristics of the word increasing intelligibility. Also, the clinician gives specific instructions about how to produce sounds correctly.

It is important to emphasize, that strategies such as modeling and modeling with stress, do not involve direct instruction on articulation placement. However, they do establish an appropriate context for focusing on specific phonemes while receiving the correct model of articulation of the targeted sounds. In contrast, all the other strategies provide information about how to manage phonemes for speech production. Based upon this statement, the strategies can be broadly divided into strategies involving direct instruction on articulation placement and strategies not involving direct instruction.

In previous reports [15, 18] children with cleft palate and compensatory articulation errors have been studied. It has been described that the level of language development and the phonological rules present in the phonological system of each child with special attention in compensatory articulation patterns should be carefully and assessed using standardized evaluation instruments. For this purpose, the children can be videotaped interacting with a trained speech pathologist during free play for 30 min. A 10-min segment is selected where a high level of verbal interaction occurred. The 10 min of interaction are transcribed verbatim to analyze the child’s phonological system and the presence of compensatory articulation. The children should undergo a speech intervention aimed to correct compensatory articulation and different approaches for the speech intervention can be compared: An approach which focuses on the phonetic or peripheral aspect of the articulation deficits and an approach based upon phonological principles, considering higher levels of linguistic organizations. It has been reported that children treated using common methods for articulatory intervention from the phonetic or peripheral stand point, [7, 21, 22] where errors in articulation are treated in a phoneme-by-phoneme basis (discrimination and production of /p/, different positions: initial,

middle and final, isolated, then in words, later in sentences) improve articulation placement regardless of persisting VPI. However, if children with compensatory articulation errors are treated through an approach based on phonological principles, the linguistic aspect of articulation is also addressed. An approach based upon phonologic principles includes the following aspects:

- a) The treatment goals were set depending on the phonological rules that are active in the child's system. [23]
- b) The intervention program was focused on the modification of groups of sounds that seemed to be treated by the child in a similar fashion. In other words, errors were attacked at the rule level, rather than at the phonetic level, for example, all plosives substituted by glottal stops.
- c) Emphasis was placed on the establishment of previously neutralized phonological contrasts. For example, the child who replaced all fricatives with stops could receive a positive response from the clinician when any fricative was used, even if place of articulation or voice errors persisted.

The goal can be conceived as establishing and maintaining new contrasts. With such goal in mind, correct production is not essential. There is much greater emphasis on the use of speech sounds for communicative purposes, rather than on the correct production of sounds as a goal in itself.

Children should be placed in small groups of similar age and speech characteristic, in order to provide opportunities for peer interaction and socialization. Only two to three children are placed in one group to maximize individual opportunities for adult modeling and other intervention prompts.

Speech Intervention usually consists of 1-h sessions, twice per week. All children should be followed until two independent examiners have agreed that compensatory articulation errors had been completely eliminated.

Table 1. Effectiveness of particular strategies and the degree of severity of the compensatory errors

Severity of Articulation Errors	More Effective Strategies
Adequate Articulation Placement	— — — —
Inconsistent Compensatory Articulation	Modeling; Modeling With Stress
Adequate Articulation Placement Within Linguistic Context	Modeling; Modeling With Stress
Adequate Articulation Only Through Direct Instruction On Articulation Placement Using Appropriate Strategies	Phonetic Changes; Cloze Procedure with Phonemic Cues; Think-Aloud in Phonemic Awareness
Adequate Articulation Placement Only on Isolated Phonemes	Phonetic Changes; Cloze Procedure with Phonemic Cues; Think-Aloud in Phonemic Awareness
Consistent Compensatory Articulation	Phonetic Changes; Cloze Procedure with Phonemic Cues

Total time of speech therapy can be considered as the time from the onset of speech therapy until the complete normalization of articulation as assessed in a phonological analysis from a free speech sample (videotape). Once articulation has been corrected, children can undergo videonasopharyngoscopy and multi-planar videofluoroscopy for pre-operative surgical planning. [24 – 26]

All the strategies promote positive changes in articulation. However, there seems to be a relationship between the effectiveness of particular strategies and the degree of severity of the compensatory errors. (See Table 1)

It should be pointed out that this relationship between effectiveness of specific strategies with severity of compensatory errors is independent of the age of the child. Moreover, the severity of the articulation errors does not correlate with age. In other words, a severe compensatory articulation disorder can occur equally in young and older children.
